**Perspectives on the role and responsibility of the data-management research community in designing, developing, using, and overseeing automated decision systems.**

BY JULIA STOYANOVICH, SERGE ABITEBOUL, BILL HOWE, H.V. JAGADISH, AND SEBASTIAN SCHELTER

## Responsible Data Management

INCORPORATING ETHICS AND legal compliance into data-driven algorithmic systems has been attracting significant attention from the computing research community, most notably under the umbrella of fair[8] and interpretable[16] machine learning. While important, much of this work has been limited in scope to the "last mile" of data analysis and has disregarded both the *system's design, development, and use life cycle* (What are we automating and why? Is the system working as intended? Are there any unforeseen consequences post-deployment?) and the *data life cycle* (Where did the data come from? How long is it valid and appropriate?). In this article, we argue two points. First, the decisions we make during data collection and preparation profoundly impact the robustness, fairness, and interpretability of the systems we build. Second, our responsibility for the operation of these systems does not stop when they are deployed.

**Example: Automated hiring systems.** To make our discussion concrete, consider the use of predictive analytics in hiring. Automated hiring systems are seeing ever broader use and are as varied as the hiring practices themselves, ranging from resume screeners that claim to identify promising applicants[a] to video and voice analysis tools that facilitate the interview process[b] and game-based assessments that promise to surface personality traits indicative of future success.[c] Bogen and Rieke[5] describe the hiring process from the employer's point of view as a series of decisions that forms a funnel, with stages corresponding to

REGULAR PAPER

## Profiling relational data: a survey

Ziawasch Abedjan[1] · Lukasz Golab[2] · Felix Naumann[3]

Received: 1 August 2014 / Revised: 5 May 2015 / Accepted: 13 May 2015 / Published online: 2 June 2015

**Abstract** Profiling data to determine metadata about a given dataset is an important and frequent activity of any IT professional and researcher and is necessary for various use-cases. It encompasses a vast array of methods to examine datasets and produce metadata. Among the simpler results are statistics, such as the number of null values and distinct values in a column, its data type, or the most frequent patterns of its data values. Metadata that are more difficult to compute involve multiple columns, namely correlations, unique column combinations, functional dependencies, and inclusion dependencies. Further techniques detect conditional properties of the dataset at hand. This survey provides a classification of data profiling tasks and comprehensively reviews the state of the art for each class. In addition, we review data profiling tools and systems from research and industry. We conclude with an outlook on the future of data profiling beyond traditional profiling tasks and beyond relational databases.

### 1 Data profiling: finding metadata

Data profiling is the set of activities and processes to determine the metadata about a given dataset. Profiling data is an important and frequent activity of any IT professional and researcher. We can safely assume that any reader of this article has engaged in the activity of data profiling, at least by eye-balling spreadsheets, database tables, XML files, etc. Possibly, more advanced techniques were used, such as keyword searching in datasets, writing structured queries, or even using dedicated data profiling tools.

Johnson gives the following definition: "Data profiling refers to the activity of creating small but informative summaries of a database" [79]. Data profiling encompasses a vast array of methods to examine datasets and produce metadata. Among the simpler results are statistics, such as the number of null values and distinct values in a column, its data type, or the most frequent patterns of its data values. Metadata that are more difficult to compute involve multiple columns, such as inclusion dependencies or functional dependencies. Also of practical interest are approximate versions of these dependencies, in particular because they are typically more efficient to compute. In this survey we preclude these and concentrate on exact methods.

Like many data management tasks, data profiling faces three challenges: *(i)* managing the input, *(ii)* performing the computation, and *(iii)* managing the output. Apart from typical data formatting issues, the first challenge addresses the problem of specifying the expected outcome, i.e., determining which profiling tasks to execute on which parts of the data. In fact, many tools require a precise specification of what to inspect. Other approaches are more open and perform a wider range of tasks, discovering all metadata automatically.

The second challenge is the main focus of this survey and that of most research in the area of data profiling: The com-

# Understand your data!

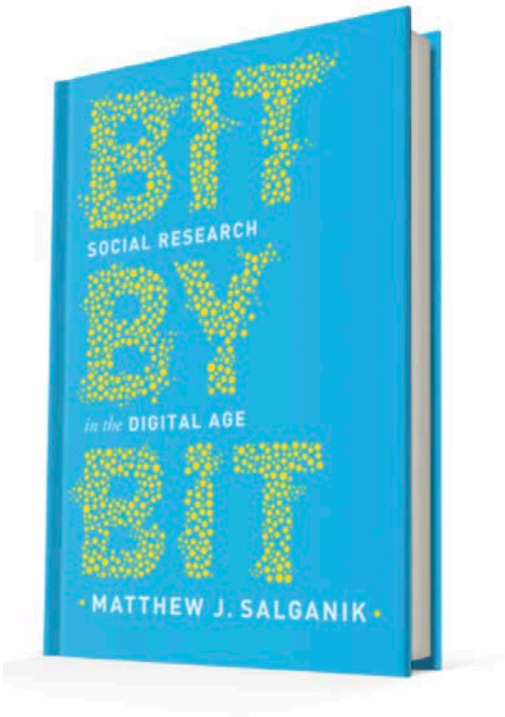
CRA
Computing Research Association

"Given the heterogeneity of the flood of data, it is **not enough merely to record it and throw it into a repository**. Consider, for example, data from a range of scientific experiments. If we just have a bunch of data sets in a repository, it is **unlikely anyone will ever be able to find, let alone reuse**, any of this data. With adequate **metadata**, there is some hope, but even so, challenges will remain due to differences in experimental details and in data record structure."

https://cra.org/ccc/wp-content/uploads/sites/2/2015/05/bigdatawhitepaper.pdf

r/ai center for responsible ai

# Understand your data!



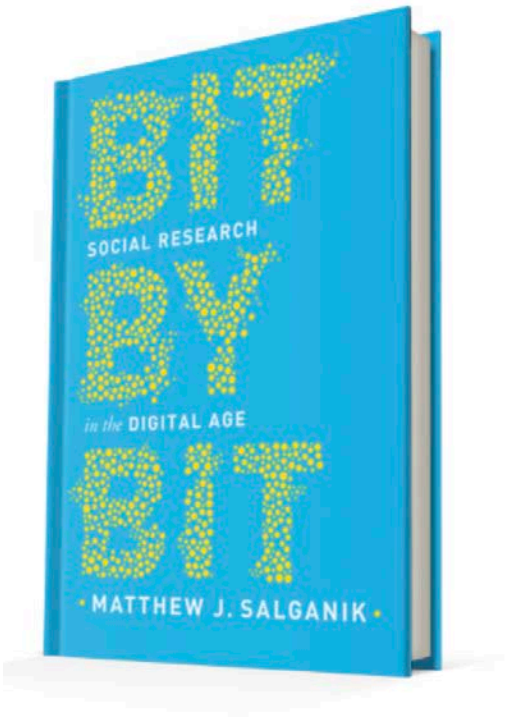
## 2.2 Big data

In the analog age, most of the data that were used for social research was created for the purpose of doing research. In the digital age, however, a huge amount of **data is being created by companies and governments for purposes other than research**, such as providing services, generating profit, and administering laws. Creative people, however, have realized that you can **repurpose** this corporate and government data for research.

https://www.bitbybitbook.com/en/1st-ed/observing-behavior/data/

r/ai center for responsible ai

# Understand your data!



**2.2 Big data**

… from the perspective of researchers, big data sources are “found,” they don’t just fall from the sky. Instead, data sources that are “found” by researchers are **designed by someone for some purpose**. Because “found” data are designed by someone, I always recommend that you **try to understand as much as possible about the people and processes that created your data**.

https://www.bitbybitbook.com/en/1st-ed/observing-behavior/data/

r/ai center for responsible ai

# Understand your data!

Need **metadata** to:

- enable data **re-use** (have to be able to find it!)
- determine **fitness for use** of a dataset in a task
- help establish **trust** in the data analysis process and its outcomes

Data is considered to be of high quality if it's "**fit for intended uses** in operations, decision making and planning"

## SAT (College Board) 2010 School Level Results

Education

Dataset

freshness

New York City school level College Board SAT results for the graduating seniors of 2010. Records contain 2010 College-bound seniors mean SAT scores.

summary

Records with 5 or fewer students are suppressed (marked 's').

privacy

College-bound seniors are those students that complete the SAT Questionnaire when they register for the SAT and identify that they will graduate from high school in a specific year. For example, the 2010 college-bound seniors are those students that self-reported they would graduate in 2010. Students are not required to complete the SAT Questionnaire in order to register for the SAT. Students who do not indicate which year they will graduate from high school will not be included in any college-bound senior report.

Students are linked to schools by identifying which school they attend when registering for a College Board exam. A student is only included in a school's report if he/she self-reports being enrolled at that school.

Data collected and processed by the College Board.

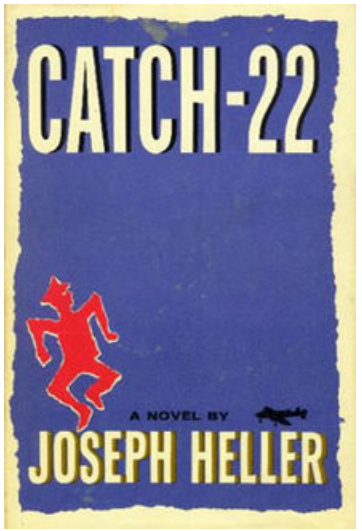
# Data profiling

- **Data profiling** refers to the activity of creating **small** but **informative** summaries of a database
- What is informative depends on the task, or set of tasks, we have in mind

**should profiling be task-agnostic or task-specific?**

A related activity is **data cleaning**



# Data cleaning

**Data cleansing** or **data cleaning** is the process of detecting and repairing corrupt or inaccurate records from a data set in order to improve the **quality of data**.

*Erhard Rahm, Hong Hai Do: Data Cleaning: Problems and Current Approaches, IEEE Data Engineering Bulletin, 2000.*

… **data** is generally considered high **quality** if it is "**fit for [its] intended uses** in operations, decision making and planning“

*Thomas C. Redman, Data Driven: Profiting from Your Most Important Business Asset. 2013*

Even though quality cannot be defined, you know what it is.

*Robert M. Prisig, Zen and the Art of Motorcycle Maintenance, 1975*

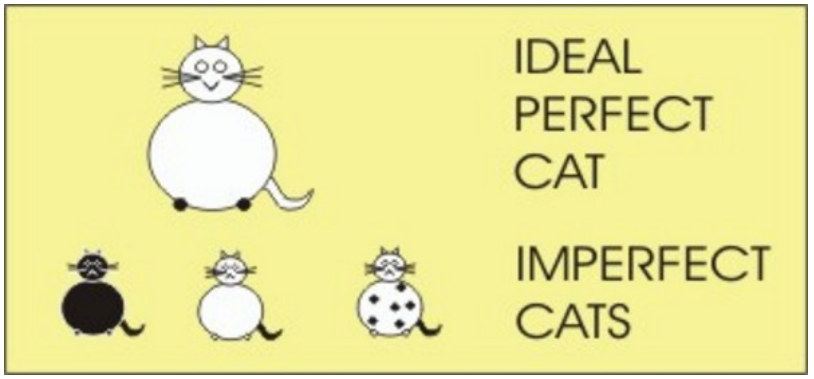
# DB (databases) vs DS (data science)



https://midnightmediamusings.wordpress.com/2014/07/01/plato-and-the-theory-of-forms/

- **DB**: start with the schema, admit only data that fits; iterative refinement is possible, and common, but we are still schema-first
- **DS**: start with the data, figure out what schema it fits, or almost fits - reasons of usability, repurposing, low start-up cost

the "right" approach is somewhere between these two, **data profiling aims to bridge** between the two world views / methodologies

[Abedjan, Golab & Naumann (2017)]

# The trouble with *null* values

A CRITIQUE OF
THE SQL DATABASE LANGUAGE

C.J.Date

PO Box 2647, Saratoga
California 95070, USA

December 1983

* Null values

I have argued against null values at length elsewhere [6], and I will not repeat those arguments here. In my opinion the null value concept is far more trouble than it is worth. Certainly it has never been properly thought through in the existing SQL implementations (see the discussion under "Lack of Orthogonality: Miscellaneous Items", earlier). For example, the fact that functions such as AVG simply ignore null values in their argument violates what should surely be a fundamental principle, viz: The system should never produce a (spuriously) precise answer to a query when the data involved in that query is itself imprecise. At least the system should offer the user the explicit option either to ignore nulls or to treat their presence as an exception.

# 50 shades of *null*

- **Unknown** - some value definitely belongs here, but I don't know what it is (e.g., unknown birthdate)
- **Inapplicable** - no value makes sense here (e.g., if marital status = single then spouse name should not have a value)
- **Unintentionally omitted** - values is left unspecified unintentionally, by mistake
- **Optional** - a value may legitimately be left unspecified (e.g., middle name)
- **Intentionally withheld** (e.g., an unlisted phone number)
- …..

(this selection is mine, see reference below for a slightly different list)

https://www.vertabelo.com/blog/technical-articles/50-shades-of-null-or-how-a-billion-dollar-mistake-has-been-stalking-a-whole-industry-for-decades

# 50 shades of *null*… and it gets worse

- **Hidden missing values** -
  - 99999 for zip code, Alabama for state
  - need data cleaning….
- lots of houses in Philadelphia, PA were built in 1934 (or 1936?) - not really!

**how do we detect hidden missing values?**

# Single column: cardinalities, data types

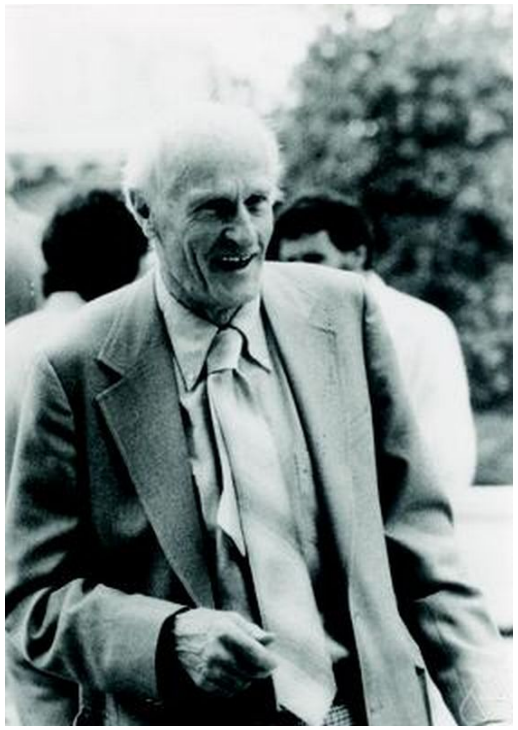
- cardinality of relation **R** - number of rows
- domain cardinality of a column **R.a** - number of **distinct** values
- attribute value **length**: min, max, average, median
- **basic data type**: string, numeric, date, time, ….
- number of percentage of **null** values of a given attribute
- **regular expressions**
- semantic domain: SSN, phone number
- ….

[Abedjan, Golab & Naumann (2015)]

# Regular expressions

- some attributes will have values that follow a regular format, e.g, telephone numbers: 212-864-0355 or (212) 864-0355 or 1.212.864-0355
- we may want to identify a small set of **regular expressions** that match all (or most) values in a column
- challenging - **very many possibilities!**

A **regular expression**, **regex** or **regexp** … is a sequence of characters that define a search pattern. Usually this pattern is used by string searching algorithms for "find" or "find and replace" operations on strings, or for input validation. It is a technique that developed in theoretical computer science and formal language theory.



Stephen Kleene

https://en.wikipedia.org/wiki/Regular_expression

# Inferring regular expressions

- we may want to identify a small set of **regular expressions** that match all (or most) values in a column
- challenging - **very many possibilities!**

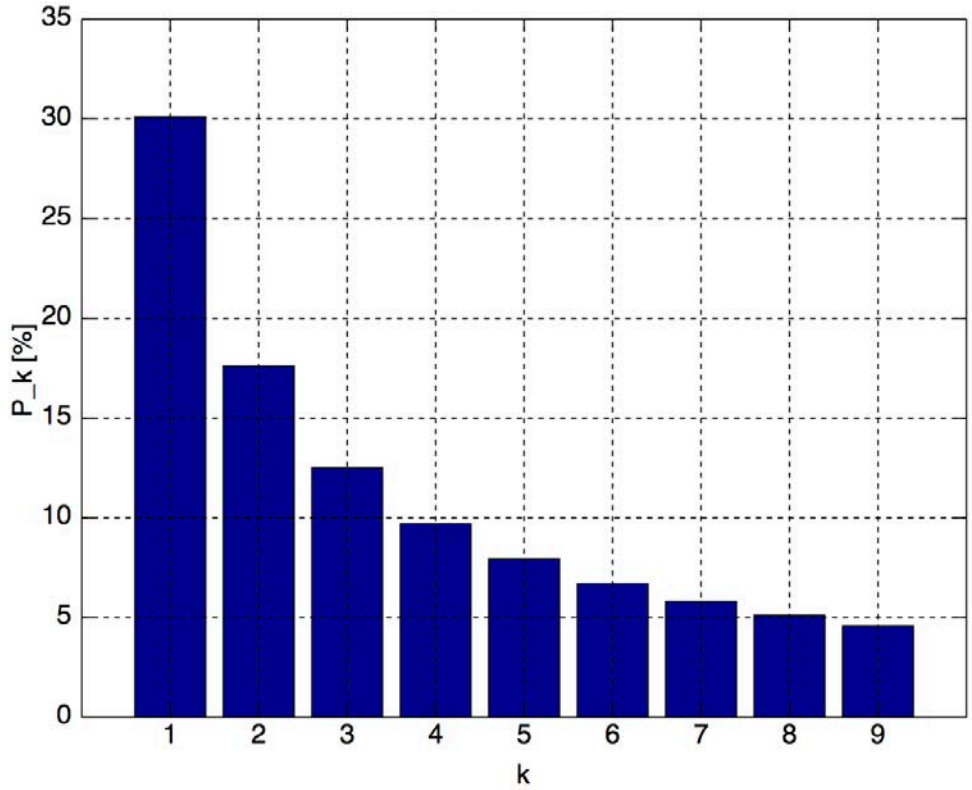
# Benford Law

The distribution of **the first digit d** of a number, in many naturally occurring domains, approximately follows

$$P(d) = \log_{10}\left(1 + \frac{1}{d}\right)$$



https://en.wikipedia.org/wiki/Benford%27s_law

1 is the most frequent leading digit, followed by 2, etc.

[Benford: "The law of anomalous numbers" *Proc. Am. Philos. Soc.*, 1938]

# Benford Law

The distribution of **the first digit d** of a number, in many naturally occurring domains, approximately follows

$$P(d) = \log_{10}\left(1 + \frac{1}{d}\right)$$

Holds if **log(x) is uniformly distributed**. **Most accurate** when values are distributed across multiple orders of magnitude, especially **if the process generating the numbers is described by a power law** (common in nature)

A logarithmic scale bar. Picking a random x position uniformly on this number line, roughly 30% of the time the first digit of the number will be 1.

https://en.wikipedia.org/wiki/Benford%27s_law

[Benford: "The law of anomalous numbers" *Proc. Am. Philos. Soc.*, 1938]

# Examples of Benford Law

- surface area of 355 rivers
- sizes of 3,259 US populations
- 104 physical constants
- 1,800 molecular weights
- 308 numbers contained in an issue of Reader's Digest
- Street addresses of the first 342 persons listed in American Men of Science

# Discovering uniques

Given a relation schema ***R*** *(A, B, C, D)* and a relation instance ***r***, a **unique column combination** (or a **"unique"** for short) is a set of attributes ***X*** whose **projection** contains no duplicates in ***r***

$Episodes(season, num, title, viewers)$

| season | num | title | viewers |
|---|---|---|---|
| 1 | 1 | Winter is Coming | 2.2 M |
| 1 | 2 | The Kingsroad | 2.2 M |
| 2 | 1 | The North Remembers | 3.9 M |

**Projection** is a relational algebra operation that takes as input relation ***R*** and returns a new relation ***R'*** with a subset of the columns of ***R***.

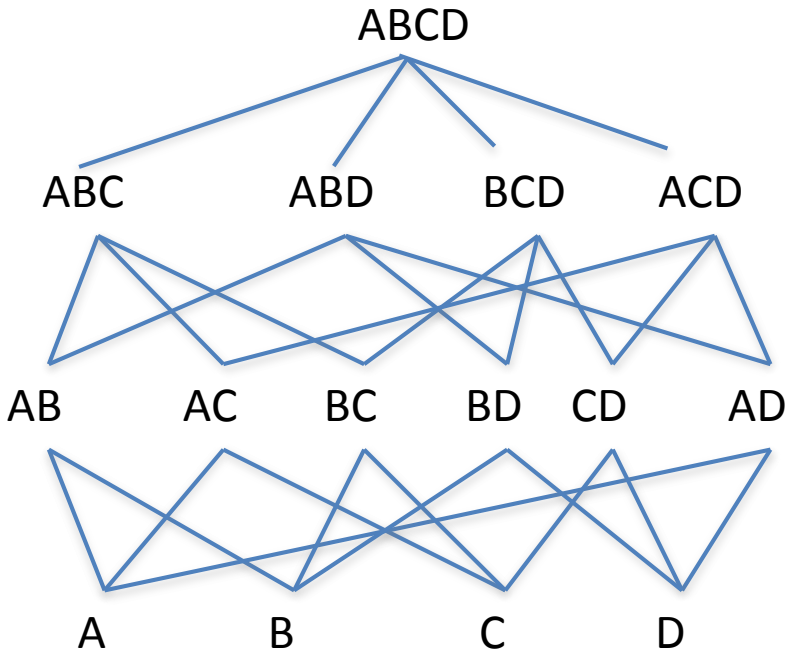
- Recall that more than one set of attributes **X** may be unique
- It may be the case that **X** and **Y** are both unique, and that they are not disjoint. When is this interesting?

# Discovering uniques

R (A, B, C, D)

attribute lattice of ***R***



$$\binom{4}{4} = 1$$

$$\binom{4}{3} = 4$$

$$\binom{4}{2} = 6$$

$$\binom{4}{1} = 4$$

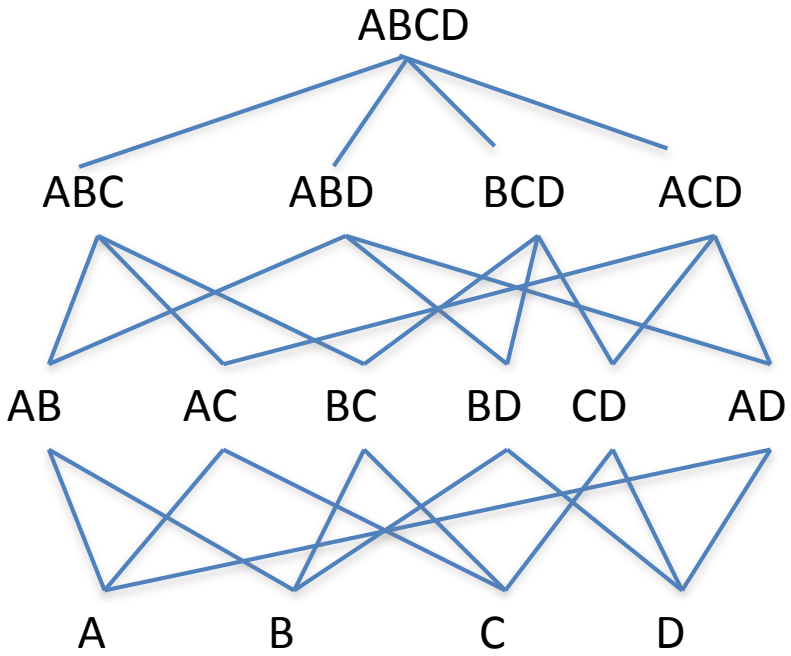
What's the size of the attribute lattice of ***R***?

**Look at all attribute combinations?**

# Discovering uniques

R (A, B, C, D)

attribute lattice of R



- If **X** is unique, then what can we say about its **superset Y**?
- If **X** is non-unique, then what can we say about its **subset Z**?

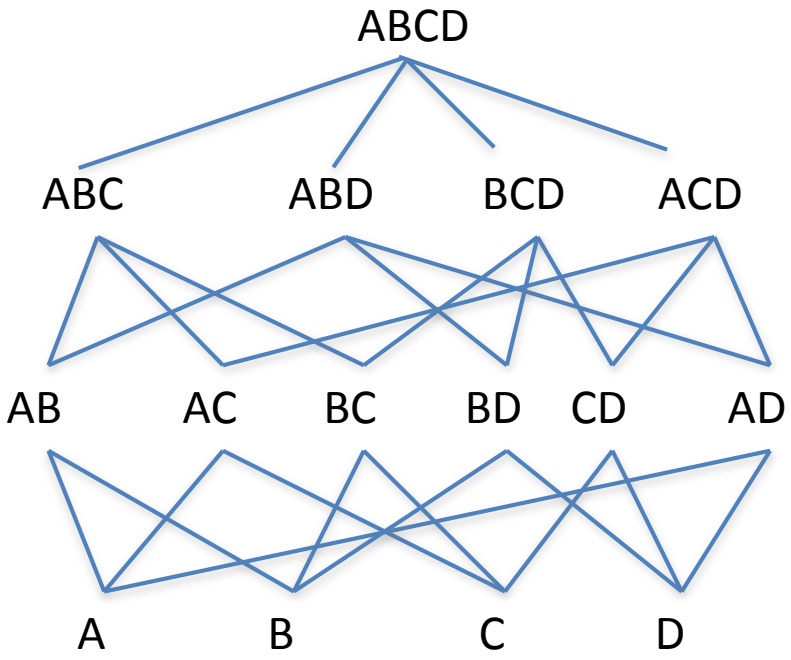
# Discovering uniques

Given a relation schema ***R*** *(A, B, C, D)* and a relation instance ***r***, a **unique column combination** (or a **"unique"** for short) is a set of attributes ***X*** whose **projection** contains no duplicates in ***r***

Given a relation schema ***R*** *(A, B, C, D)* and a relation instance ***r***, a set of attributes ***Y*** is **non-unique** if its projection contains duplicates in ***r***

***X*** is **minimal unique** if every subset ***Y*** of ***X*** is non-unique

***Y*** is maximal non-unique if every superset ***X*** of ***Y*** is unique



# From uniques to candidate keys

Given a relation schema ***R*** *(A, B, C, D)* and a relation instance ***r***, a **unique column combination** is a set of attributes ***X*** whose **projection** contains no duplicates in ***r***

$$Episodes(season, num, title, viewers)$$

| season | num | title | viewers |
|---|---|---|---|
| 1 | 1 | Winter is Coming | 2.2 M |
| 1 | 2 | The Kingsroad | 2.2 M |
| 2 | 1 | The North Remembers | 3.9 M |

A set of attributes is a **candidate key** for a relation if:
(1) no two distinct tuples can have the same values for all key attributes (candidate key **uniquely identifies** a tuple), *and*
(2) this is not true for any subset of the key attributes (candidate key **is minimal**)

**A minimal unique of a relation instance is a (possible) candidate key of the relation schema.** To find all possible candidate keys, find all minimal uniques in a relation instance.

r/ai center for responsible ai

# The early days of data mining

- Problem formulation due to Agrawal, Imielinski, Swami, SIGMOD 1993
- Solution: the **Apriori** algorithm by Agrawal & Srikant, VLDB 1994
- Initially for **market-basket data** analysis, has many other applications, we'll see one today
- We wish to answer two related questions:
  - **Frequent itemsets:** Which items are often purchased together, e.g., milk and cookies are often bought together
  - **Association rules:** Which items will likely be purchased, based on other purchased items, e.g., if diapers are bought in a transaction, beer is also likely bought in the same transaction

# Market-basket data

- $I = \{i_1, i_2, \ldots, i_m\}$ is the set of available items, e.g., a product catalog of a store
- $X \subseteq I$ is an **itemset**, e.g., {milk, bread, cereal}
- **Transaction** $t$ is a set of items purchased together, $t \subseteq I$, has a transaction id (TID)

  $t_1$: {bread, cheese, milk}

  $t_2$: {apple, eggs, salt, yogurt}

  $t_3$: {biscuit, cheese, eggs, milk}
- Database $T$ is a set of transactions $\{t_1, t_2, \ldots, t_n\}$
- A transaction $t$ **supports** an itemset $X$ if $X \subseteq t$
- Itemsets supported by at least ***minSupp*** transactions are called **frequent itemsets**

**minSupp, which can be a number or a percentage, is specified by the user**

# Itemsets

| TID | Items |
|---|---|
| 1 | A |
| 2 | A C |
| 3 | A B D |
| 4 | A C |
| 5 | A B C |
| 6 | A B C |

***minSupp*** = 2 transactions

How many possible itemsets are there (excluding the empty itemset)?

$2^4 - 1 = 15$

| itemset | support |
|---|---|
| ★ A | 6 |
| ★ B | 3 |
| ★ C | 4 |
| D | 1 |
| ★ A B | 3 |
| ★ A C | 4 |
| A D | 1 |
| ★ B C | 2 |
| B D | 1 |
| C D | 0 |
| ★ A B C | 2 |
| A B D | 1 |
| B C D | 0 |
| A C D | 0 |
| A B C D | 0 |

# Association rules

An **association rule** is an implication $X \rightarrow Y$, where $X, Y \subset I$, *and* $X \cap Y = \varnothing$

example: {milk, bread} → {cereal}

"A customer who purchased X is also likely to have purchased Y in the same transaction"

we are interested in rules with a **single item** in Y

can we represent {milk, bread} → {cereal, cheese}?

Rule $X \rightarrow Y$ holds with **support** *supp* in T if *supp* of transactions contain $X \cup Y$

Rule $X \rightarrow Y$ holds with confidence *conf* in T if *conf* % of transactions that contain X also contain Y

$conf \approx \Pr(Y \mid X)$

$conf\ (X \rightarrow Y) = supp\ (X \cup Y)\ /\ supp\ (X)$

# Association rules

***minSupp*** = 2 transactions
***minConf*** = 0.75

| itemset | support |
|---|---|
| A | 6 |
| B | 3 |
| C | 4 |
| D | 1 |
| A B | 3 |
| A C | 4 |
| A D | 1 |
| B C | 2 |
| B D | 1 |
| C D | 0 |
| A B C | 2 |
| A B D | 1 |
| B C D | 0 |
| A C D | 0 |
| A B C D | 0 |

supp = 3
$A \rightarrow B$ conf = 3 / 6 = 0.5
$B \rightarrow A$ conf = 3 / 3 = 1.0 ★

supp = 2
$B \rightarrow C$ conf = 2 / 3 = 0.67
$C \rightarrow B$ conf = 2 / 4 = 0.5

supp = 4
$A \rightarrow C$ conf = 4 / 6 = 0.67
$C \rightarrow A$ conf = 4 / 4 = 1.0 ★

supp = 2
$AB \rightarrow C$ conf = 2 / 3 = 0.67
$AC \rightarrow B$ conf = 2 / 4 = 0.5
$BC \rightarrow A$ conf = 2 / 2 = 1.0 ★

$$conf(X \rightarrow Y) = supp(X \cup Y) / supp(X)$$

# Association rule mining

- Goal: find all association rules that satisfy the user-specified minimum support and minimum confidence

- Algorithm outline
  - Step 1: find all frequent itemsets
  - Step 2: find association rules

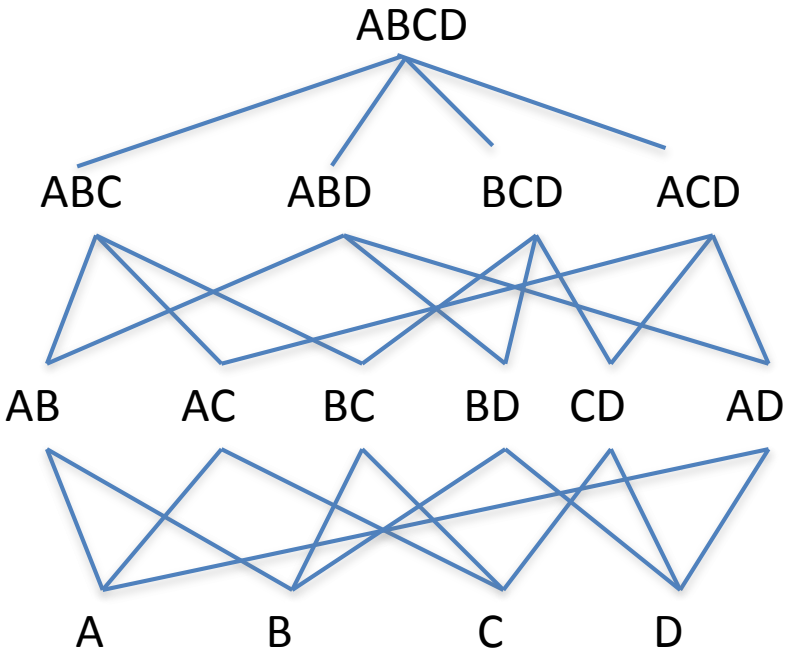
- Take 1: naïve algorithm for frequent itemset mining
  - Enumerate all subsets of ***I***, check their support in ***T***
  - **What is the complexity?**

# Key idea: downward closure

| itemset | support |
|---|---|
| ★ A | 6 |
| ★ B | 3 |
| ★ C | 4 |
| D | 1 |
| ★ A B | 3 |
| ★ A C | 4 |
| A D | 1 |
| ★ B C | 2 |
| B D | 1 |
| C D | 0 |
| ★ A B C | 2 |
| A B D | 1 |
| B C D | 0 |
| A C D | 0 |
| A B C D | 0 |

All subsets of a frequent itemset ***X*** are themselves frequent

So, if some subset of X is infrequent, then X cannot be frequent, we know this **apriori**



The converse is not true! If all subsets of ***X*** are frequent, ***X*** is not guaranteed to be frequent

# The *Apriori* algorithm

**Algorithm Apriori(*T*, *minSupp*)**

$F_1$ = {*frequent 1-itemsets*};

**for** ($k$ = 2; $F_{k-1} \neq \emptyset$; $k$++) **do**

$C_k \leftarrow$ **candidate-gen**($F_{k-1}$);

**for** each transaction $t \in T$ **do**

**for** each candidate $c \in C_k$ **do**

**if** $c$ is contained in $t$ **then**

*c.count*++;

**end**

**end**

$F_k \leftarrow \{c \in C_k \mid c.count \geq minSupp\}$

**end**

return $F \leftarrow \bigcup_k F_k$;

| | itemset | support |
|---|---|---|
| ★ | A | 6 |
| ★ | B | 3 |
| ★ | C | 4 |

# Candidate generation

Assume a lexicographic ordering of the items

**Join**

```
Insert into C_k (
   select   p.item_1, p.item_2, …, p.item_{k-1}, q.item_{k-1}
   from     F_{k-1} p, F_{k-1} q
   where    p.item_1 = q.item_1
   and      p.item_2 = q.item_2
   and      …
   and      p.item_{k-1} < q.item_{k-1} )
```

**why not p.item$_{k-1}$ ≠ q.item$_{k-1}$?**

**Prune**

**for** each c in $C_k$ **do**
  **for** each (k-1) subset s of c **do**
    **if** (s not in $F_{k-1}$) **then**
      delete c from $C_k$

# Generating association rules

Rules = ∅

**for** each frequent *k-itemset* X **do**

  **for** each 1-itemset A ⊂ X **do**

    compute conf (X / A → A) = supp(X) / sup (X / A)

    **if** conf (X / A → A) ≥ minConf **then**

      *Rules* ← "X / A → A"

  **end**

**end**

**end**

**return** Rules

# Performance of *Apriori*

- The possible number of frequent itemsets is exponential, O($2^m$), where $m$ is the number of items
- Apriori exploits sparseness and locality of data
  - Still, it may produce a large number of rules: thousands, tens of thousands, ….
  - So, thresholds should be set carefully. What are some good heuristics?

**Abstract**

*Machine Learning (ML) is commonly used to automate decisions in domains as varied as credit and lending, medical diagnosis, and hiring. These decisions are consequential, imploring us to carefully balance the benefits of efficiency with the potential risks. Much of the conversation about the risks centers around bias — a term that is used by the technical community ever more frequently but that is still poorly understood. In this paper we focus on technical bias — a type of bias that has so far received limited attention and that the data engineering community is well-equipped to address. We discuss dimensions of technical bias that can arise through the ML lifecycle, particularly when it's due to preprocessing decisions or post-deployment issues. We present results of our recent work, and discuss future research directions. Our over-all goal is to support the development of systems that expose the knobs of responsibility to data scientists, allowing them to detect instances of technical bias and to mitigate it when possible.*

### 1 Introduction

Machine Learning (ML) is increasingly used to automate decisions that impact people's lives, in domains as varied as credit and lending, medical diagnosis, and hiring. The risks and opportunities arising from the wide-spread use of predictive analytics are garnering much attention from policy makers, scientists, and the media. Much of this conversation centers around *bias* — a term that is used by the technical community ever more frequently but that is still poorly understood.

In their seminal 1996 paper, Friedman and Nissenbaum identified three types of bias that can arise in computer systems: pre-existing, technical, and emergent [9]. We briefly discuss these in turn, see Stoyanovich et al. [33] for a more comprehensive overview.

- *Pre-existing bias* has its origins in society. In ML applications, this type of bias often exhibits itself in the input data; detecting and mitigating it is the subject of much research under the heading of algorithmic fairness [5]. Importantly, the presence or absence of pre-existing bias cannot be scientifically verified, but rather is postulated based on a belief system [8, 12]. Consequently, the effectiveness — or even the validity — of a technical attempt to mitigate pre-existing bias is predicated on that belief system.

SPECIAL ISSUE PAPER

## Data distribution debugging in machine learning pipelines

Stefan Grafberger[1] · Paul Groth[1] · Julia Stoyanovich[2] · Sebastian Schelter[1]

Received: 27 February 2021 / Revised: 9 September 2021 / Accepted: 3 December 2021

**Abstract**
Machine learning (ML) is increasingly used to automate impactful decisions, and the risks arising from this widespread use are garnering attention from policy makers, scientists, and the media. ML applications are often brittle with respect to their input data, which leads to concerns about their correctness, reliability, and fairness. In this paper, we describe `mlinspect`, a library that helps diagnose and mitigate technical bias that may arise during preprocessing steps in an ML pipeline. We refer to these problems collectively as *data distribution bugs*. The key idea is to extract a directed acyclic graph representation of the dataflow from a preprocessing pipeline and to use this representation to automatically instrument the code with predefined *inspections*. These inspections are based on a lightweight annotation propagation approach to propagate metadata such as lineage information from operator to operator. In contrast to existing work, `mlinspect` operates on declarative abstractions of popular data science libraries like estimator/transformer pipelines and does not require manual code instrumentation. We discuss the design and implementation of the `mlinspect` library and give a comprehensive end-to-end example that illustrates its functionality.

### 1 Introduction

Machine learning (ML) is increasingly used to automate decisions that impact people's lives, in domains as varied as credit and lending, medical diagnosis, and hiring, with the potential to reduce costs, reduce errors, and make outcomes more equitable. Yet, despite their potential, the risks arising from the widespread use of ML-based tools are garnering attention from policy makers, scientists, and the media [52]. In large part this is because the correctness, reliability, and fairness of ML models critically depend on their training data. Preexisting bias, such as under- or over-representation of particular groups in the training data [12], and technical bias, such as skew introduced during data preparation [49], can heavily impact performance. In this work, we focus on helping diagnose and mitigate technical bias that arises during preprocessing steps in an ML pipeline. We refer to these problems collectively as *data distribution bugs*.

**Data distribution bugs are often introduced during preprocessing** Input data for ML applications come from a variety of data sources, and it has to be preprocessed and encoded as features before it can be used. This preprocessing can introduce skew in the data, and, in particular, it can exacerbate under-representation of historically disadvantaged groups. For example, preprocessing operations that involve filters or joins can heavily change the distribution of different groups represented in the training data [58], and missing value imputation can also introduce skew [47]. Recent ML fairness research, which mostly focuses on the use of learning algorithms on static datasets [14], is therefore insufficient because it cannot address such technical bias originating from the data preparation stage. Furthermore, it is important to detect and mitigate bias as close to its source as possible [52].

**Data distribution bugs are difficult to catch** In part, this is because different pipeline steps are implemented using different libraries and abstractions, and data representation often

# Recall: 50 shades of *null*

- **Unknown** - some value definitely belongs here, but I don't know what it is (e.g., unknown birthdate)
- **Inapplicable** - no value makes sense here (e.g., if marital status = single then spouse name should not have a value)
- **Unintentionally omitted** - values is left unspecified unintentionally, by mistake
- **Optional** - a value may legitimately be left unspecified (e.g., middle name)
- **Intentionally withheld** (e.g., an unlisted phone number)
- …..

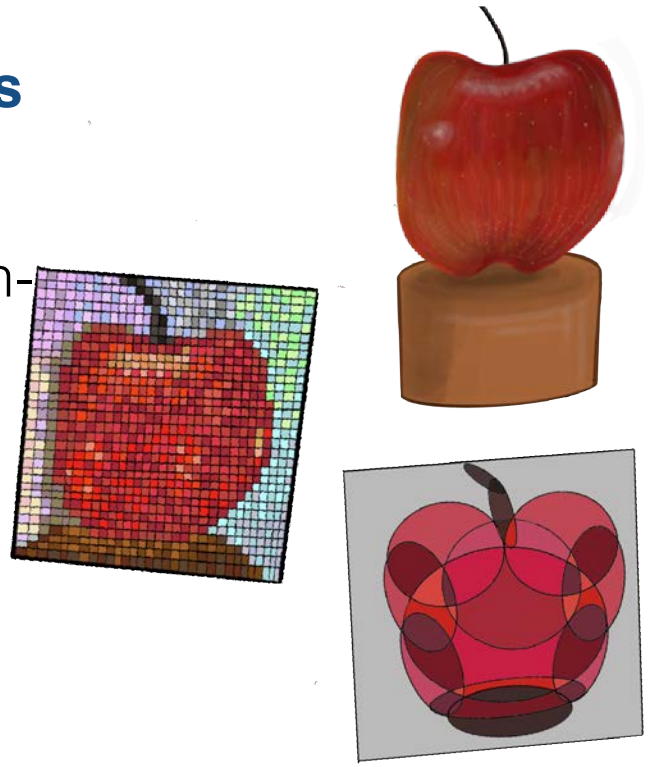
# Missing value imputation

are values **missing at random** (e.g., gender, age, disability on job applications)?

are we ever interpolating **rare categories** (e.g., Native American)

are **all categories** represented (e.g., non-binary gender)?



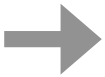
# Data filtering

"filtering" operations (like selection and join), **can arbitrarily change demographic group proportions**

select by zip code, country, years of C++ experience, others?

| age_group | county |
|---|---|
| 60 | CountyA |
| 60 | CountyA |
| 20 | CountyA |
| 60 | CountyB |
| 20 | CountyB |
| 20 | CountyB |

50% vs 50%



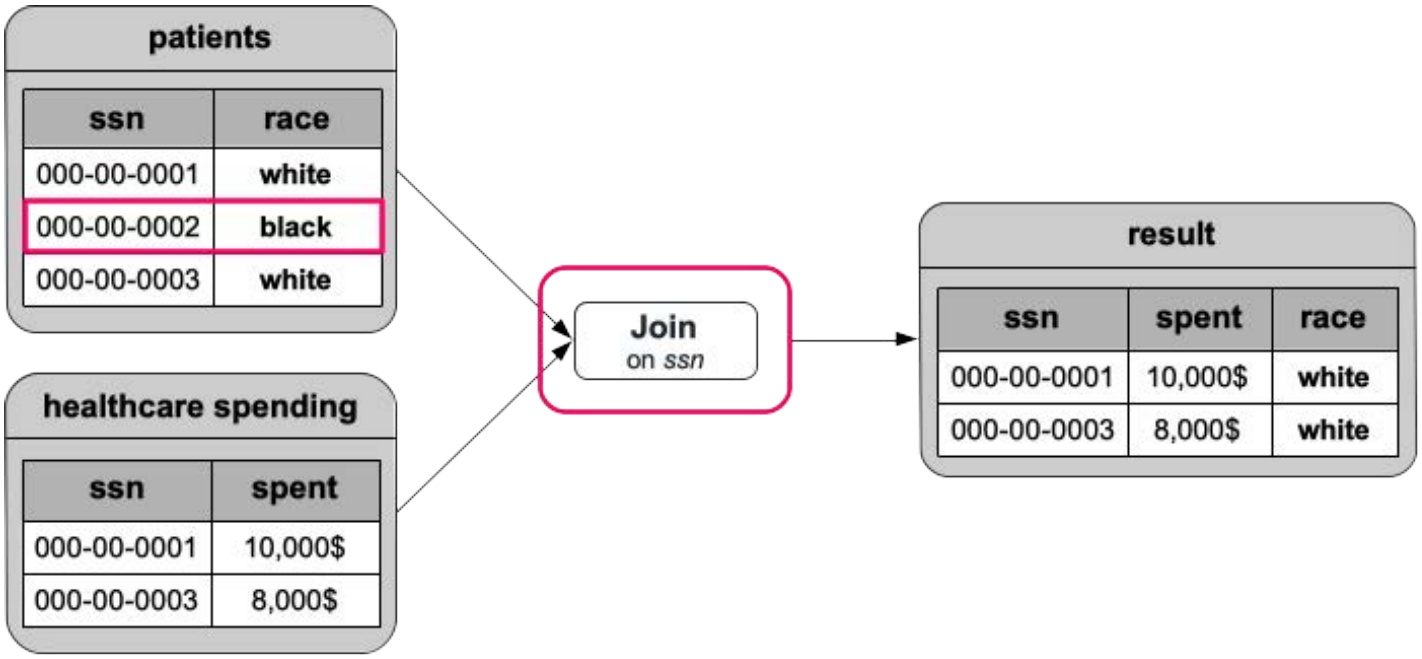
| age_group | county |
|---|---|
| 60 | CountyA |
| 60 | CountyA |
| 20 | CountyA |

66% vs 33%

# Data filtering

"filtering" operations (like selection and join), **can arbitrarily change demographic group proportions**

select by zip code, country, years of C++ experience, others?



# Data distribution debugging: mlinspect

**Potential issues in preprocessing pipeline:**

1. Join might change proportions of groups in data
2. Column 'age_group' projected out, but required for fairness
3. Selection might change proportions of groups in data
4. Imputation might change proportions of groups in data
5. 'race' as a feature might be illegal!
6. Embedding vectors may not be available for rare names!

**Python script for preprocessing, written exclusively with native pandas and sklearn constructs**

```
# load input data sources, join to single table
patients = pandas.read_csv(…)
histories = pandas.read_csv(…)
data = pandas.merge([patients, histories], on=['ssn'])

# compute mean complications per age group, append as column
complications = data.groupby('age_group')
  .agg(mean_complications=('complications','mean'))
data = data.merge(complications, on=['age_group'])

# Target variable: people with frequent complications
data['label'] = data['complications'] >
  1.2 * data['mean_complications']

# Project data to subset of attributes, filter by counties
data = data[['smoker', 'last_name', 'county',
             'num_children', 'race', 'income', 'label']]
data = data[data['county'].isin(counties_of_interest)]

# Define a nested feature encoding pipeline for the data
impute_and_encode = sklearn.Pipeline([
  (sklearn.SimpleImputer(strategy='most_frequent')),
  (sklearn.OneHotEncoder())])
featurisation = sklearn.ColumnTransformer(transformers=[
  (impute_and_encode, ['smoker', 'county', 'race']),
  (Word2VecTransformer(), 'last_name')
  (sklearn.StandardScaler(), ['num_children', 'income']])

# Define the training pipeline for the model
neural_net = sklearn.KerasClassifier(build_fn=create_model())
pipeline = sklearn.Pipeline([
  ('features', featurisation),
  ('learning_algorithm', neural_net)])

# Train-test split, model training and evaluation
train_data, test_data = train_test_split(data)
model = pipeline.fit(train_data, train_data.label)
print(model.score(test_data, test_data.label))
```

**Declarative inspection of preprocessing pipeline**

```
mlinspect
PipelineInspector
 .on_pipeline('health.py')
  .no_bias_introduced_for(
  ['age_group', 'race'])
  .no_illegal_features()
  .no_missing_embeddings()
 .verify()
```
