# Online job ads

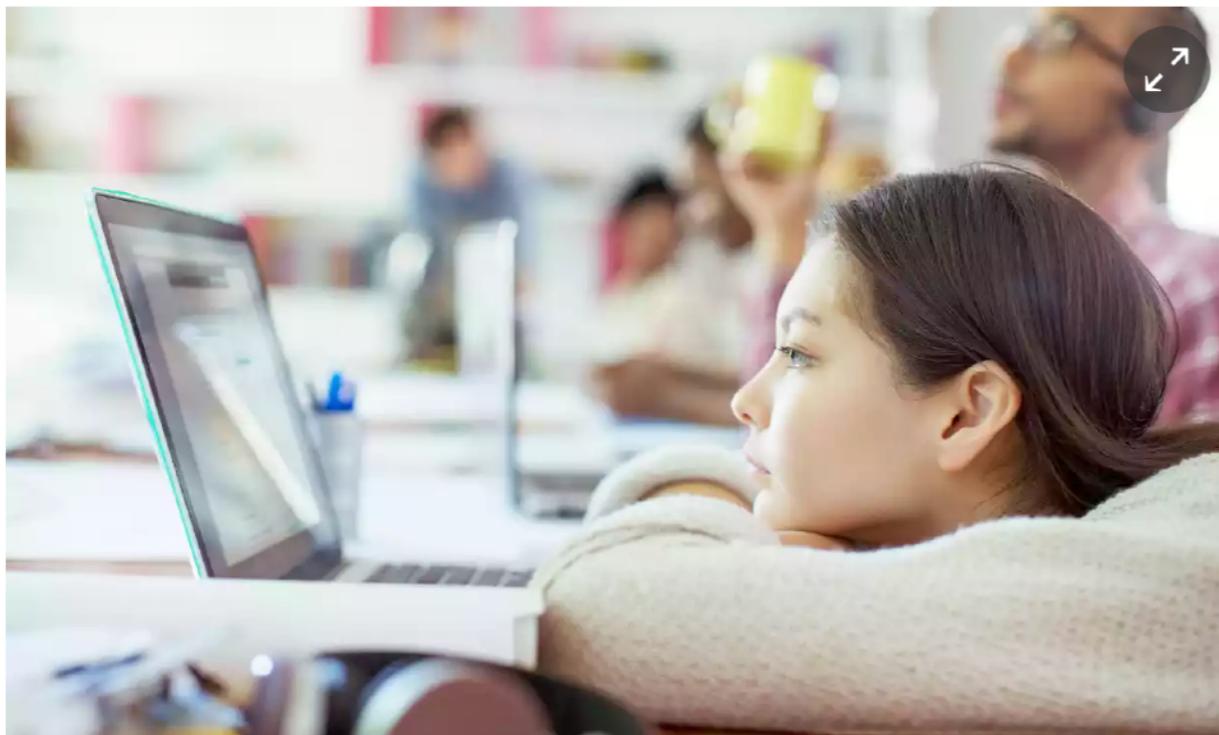

the guardian

Samuel Gibbs

Wednesday 8 July 2015 11.29 BST

## Women less likely to be shown ads for high-paid jobs on Google, study shows

Automated testing and analysis of company's advertising system reveals male job seekers are shown far more adverts for high-paying executive jobs

One experiment showed that Google displayed adverts for a career coaching service for executive jobs 1,852 times to the male group and only 318 times to the female group. Photograph: Alamy

The AdFisher tool simulated job seekers that did not differ in browsing behavior, preferences or demographic characteristics, except in gender.

One experiment showed that Google displayed ads for a career coaching service for “\$200k+” executive jobs **1,852 times to the male group and only 318 times to the female group**. Another experiment, in July 2014, showed a similar trend but was not statistically significant.

- **Online ad targeting**
  - Racially identifying names [Sweeney, CACM 2013]
  - Ad Fisher [Datta et al., PoPETs 2015]
  - Facebook's ad delivery [Ali et al., ACM CSCW 2019]
- **Interpretability**
  - Nutritional labels [Stoyanovich & Howe, IEEE DE Bull 2019]  
[Stoyanovich, Van Bavel, West, Nature Machine Intelligence 2020]

# “Why should I trust you?” Explaining the predictions of any classifier (**LIME**)

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

# Interpretability enables trust

- **If users do not trust a model or a prediction, they will not use it!**
  - predictive models are bound to make mistakes (recall our discussion of fairness in risk assessment)
  - in many domains (e.g., medical diagnosis, terrorism detection, setting global policy, ....) consequences of a mistake may be catastrophic
  - think **agency** and **responsibility**

# Interpretability enables trust

- The authors of LIME distinguish between two related definitions of trust:
  - trusting **a prediction** sufficiently to take some action based on it
  - trusting **a model** to behave in a reasonable way when it is deployed
- Of course, trusting **data** plays into both of these - garbage in / garbage out (recall our discussion of data profiling)

**Is accuracy sufficient for trust?**

# Detour: Facebook's real-name policy

## Facebook Thinks Some Native American Names Are Inauthentic

BY JOSH SANBURN FEBRUARY 14, 2015

If you're Native American, Facebook might think your name is fake.

February 14, 2015

The social network has a history of telling its users that the names they're attempting to use aren't real. Drag queens and overseas human rights activists, for example, have experienced error messages and problems logging in in the past.

The latest flap involves Native Americans, including Dana Lone Hill, who is Lakota. Lone Hill recently wrote in a blog post that Facebook told her her name was not "authentic" when she attempted to log in.

# When is accuracy insufficient for trust?

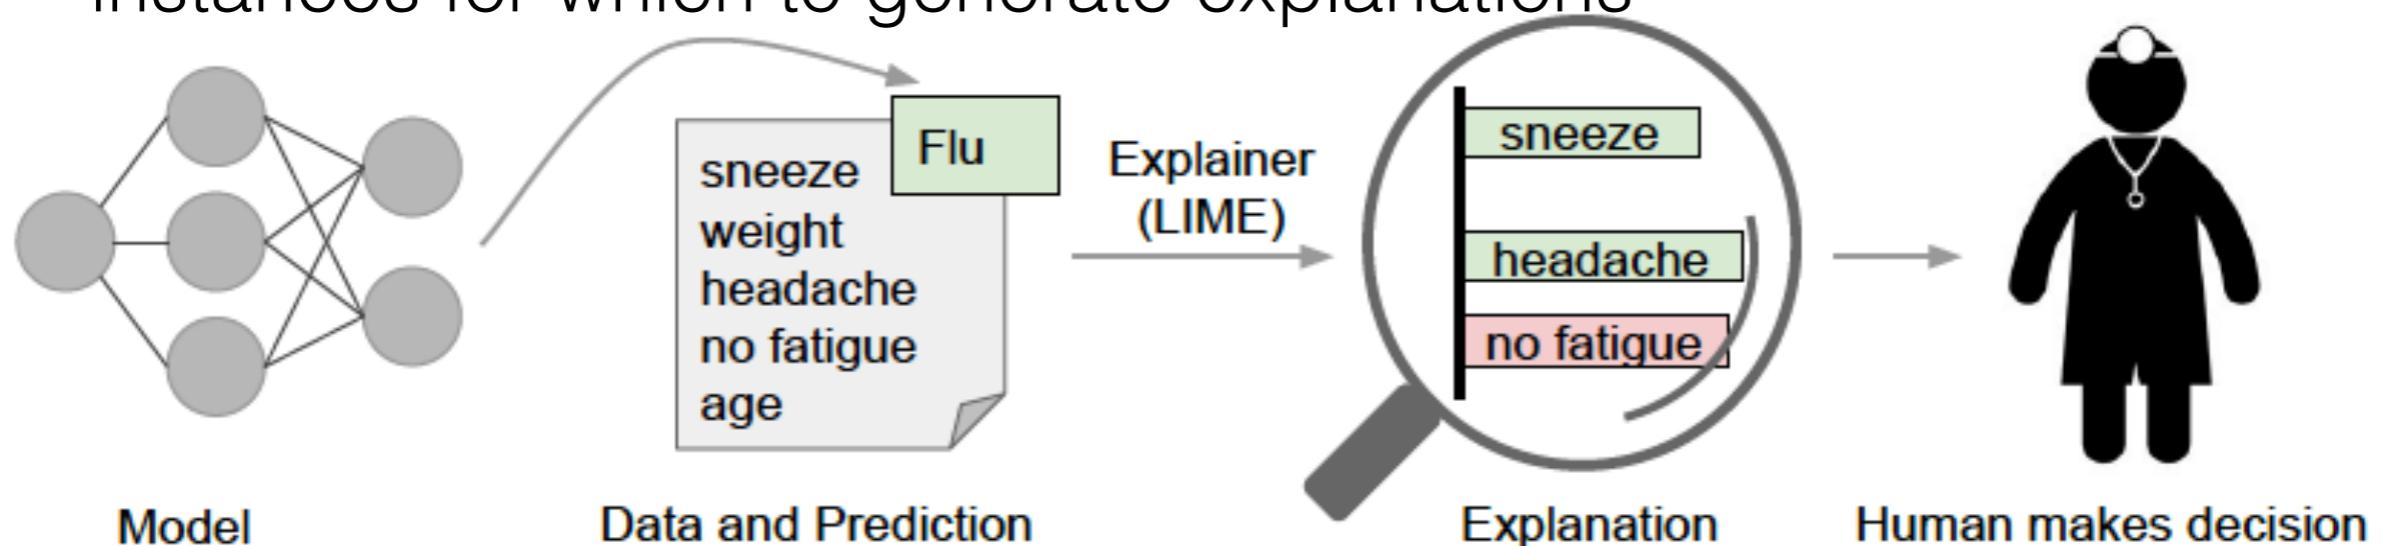

## Important questions

- how is accuracy measured?
- accuracy for whom? overall or in sub-populations?
- accuracy over which data?
- mistakes for what reason?

# Explanations based on features

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

- **LIME** (Local Interpretable Model-Agnostic Explanations): to help users trust a prediction, explain individual predictions
- **SP-LIME**: to help users trust a model, select a set of representative instances for which to generate explanations

features in green (“sneeze”, “headache”) support the prediction (“Flu”), while features in red (“no fatigue”) are evidence against the prediction

**what if patient id appears in green in the list? - an example of “data leakage”**

# LIME: Local explanations of classifiers

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

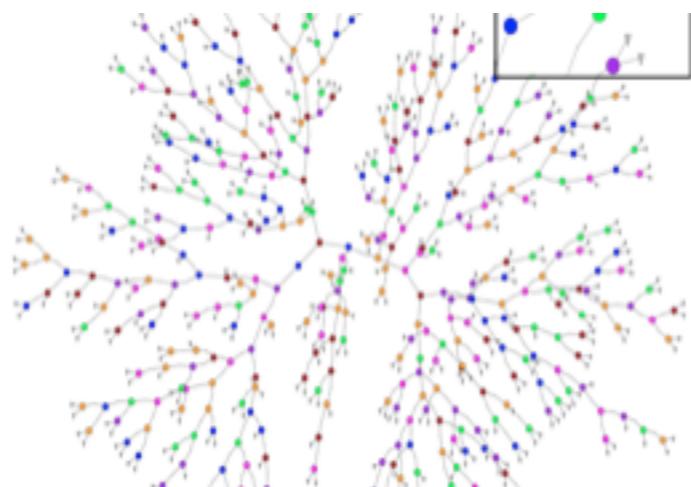

<https://www.youtube.com/watch?v=hUnRCxnydCc>

Three must-haves for a good explanation

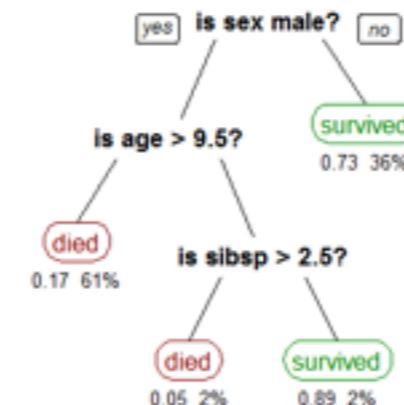

Interpretable

- Humans can easily interpret reasoning

**what's interpretable depends on who the user is**

Definitely  
not interpretable

Potentially  
interpretable

# LIME: Local explanations of classifiers

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

<https://www.youtube.com/watch?v=hUnRCxnydCc>

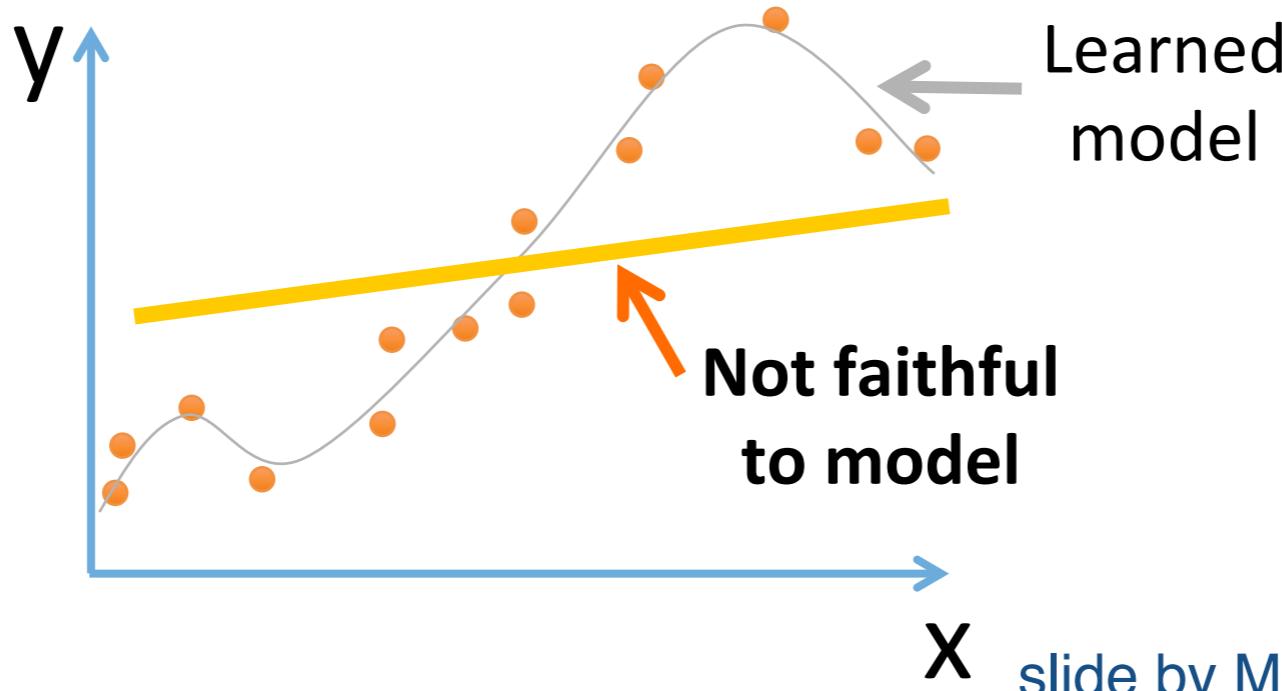

Three must-haves for a good explanation

Interpretable

- Humans can easily interpret reasoning

Faithful

- Describes how this model actually behaves

Model agnostic

- Can be used for *any* ML model

Can explain  
this mess ☺

slide by Marco Tulio Ribeiro, KDD 2016

# Key idea: Interpretable representation

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

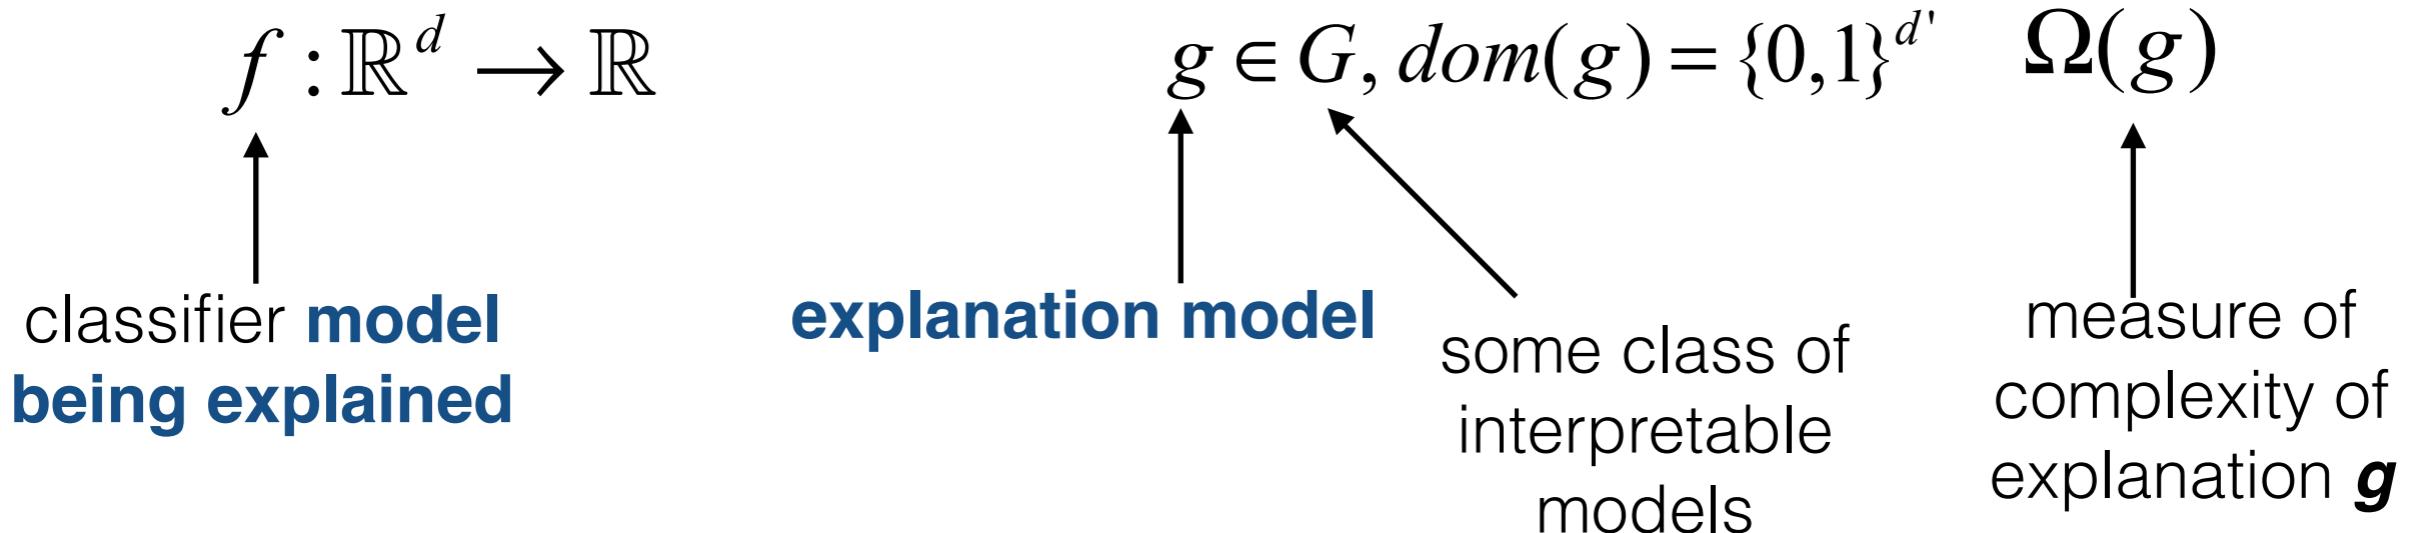

“The overall goal of LIME is to identify an **interpretable** model over the *interpretable representation* that is **locally faithful** to the classifier.”

- LIME relies on a distinction between **features** and **interpretable data representations**; examples:
  - In text classification features are word embeddings; an interpretable representation is a vector indicating the presence or absence of a word
  - In image classification features encoded in a tensor with three color channels per pixel; an interpretable representation is a binary vector indicating the presence or absence of a contiguous patch of similar pixels
- **To summarize:** we may have some  $\mathbf{d}$  features and  $\mathbf{d}'$  interpretable components; interpretable models will act over domain  $\{\mathbf{0}, \mathbf{1}\}^{\mathbf{d}'}$  - denoting the presence or absence of each of  $\mathbf{d}'$  interpretable components

# Fidelity-interpretability trade-off

[M. T. Ribeiro, S. Singh, C. Guestrin; KDD 2016]

“The overall goal of LIME is to identify an **interpretable** model over the *interpretable representation* that is **locally faithful** to the classifier.”

$f(x)$  denotes the probability that  $\mathbf{x}$  belongs to some class

$\pi_x$  is a **proximity measure** relative to  $\mathbf{x}$

we make no assumptions about  $\mathbf{f}$  to remain model-agnostic: draw samples weighted by  $\pi_x$

**explanation**

$$\xi(x) = \operatorname{argmin}_{g \in G} L(f, g, \pi_x) + \Omega(g)$$

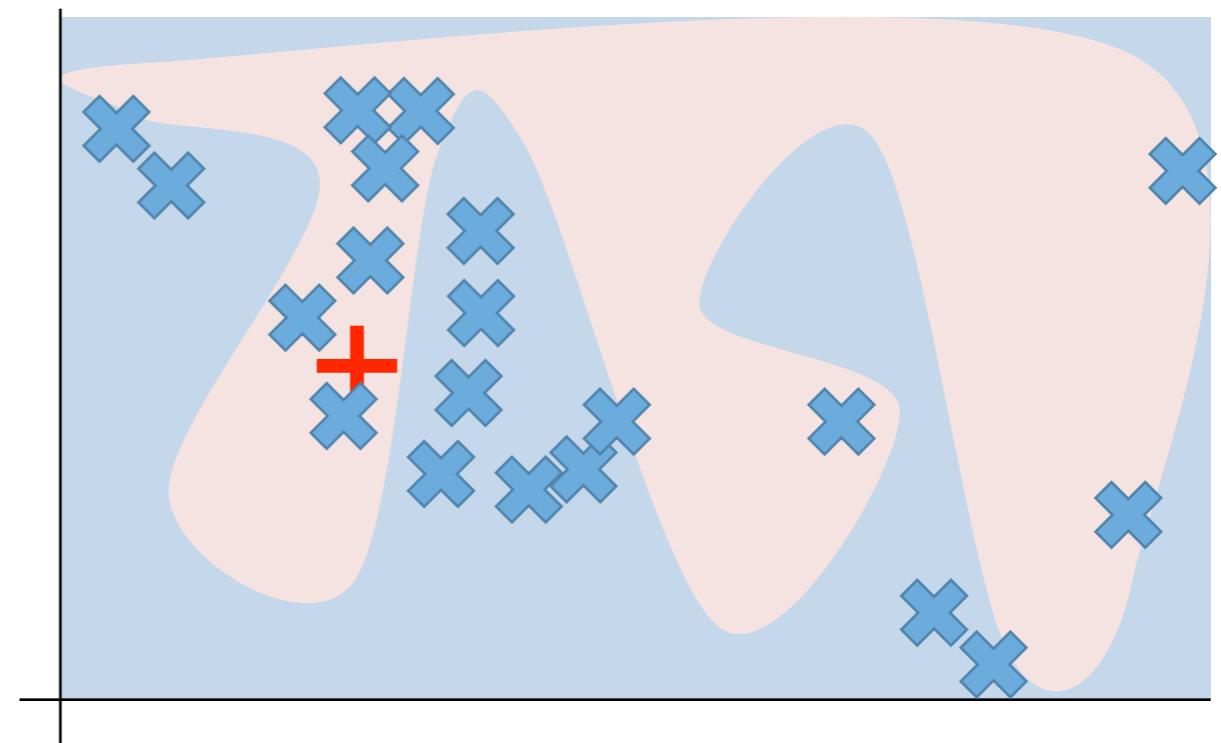

measures how unfaithful is  $g$  to  $\mathbf{f}$  in the locality around  $\mathbf{x}$

# Fidelity-interpretability trade-off

[M. T. Ribeiro, S. Singh, C. Guestrin; KDD 2016]

“The overall goal of LIME is to identify an **interpretable** model over the *interpretable representation* that is **locally faithful** to the classifier.”

1. sample points around 

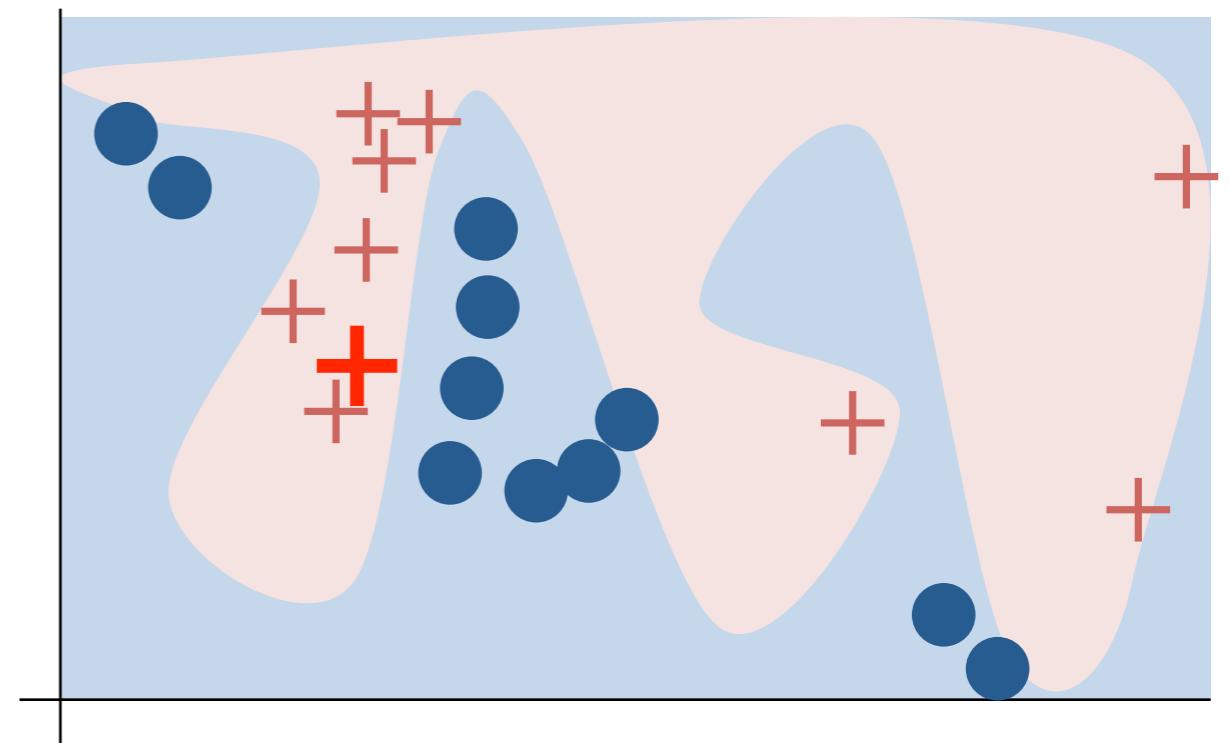

based on a slide by Marco Tulio Ribeiro, KDD 2016

# Fidelity-interpretability trade-off

[M. T. Ribeiro, S. Singh, C. Guestrin; KDD 2016]

“The overall goal of LIME is to identify an **interpretable** model over the *interpretable representation* that is **locally faithful** to the classifier.”

1. sample points around 
2. use complex model  $f$  to assign class labels

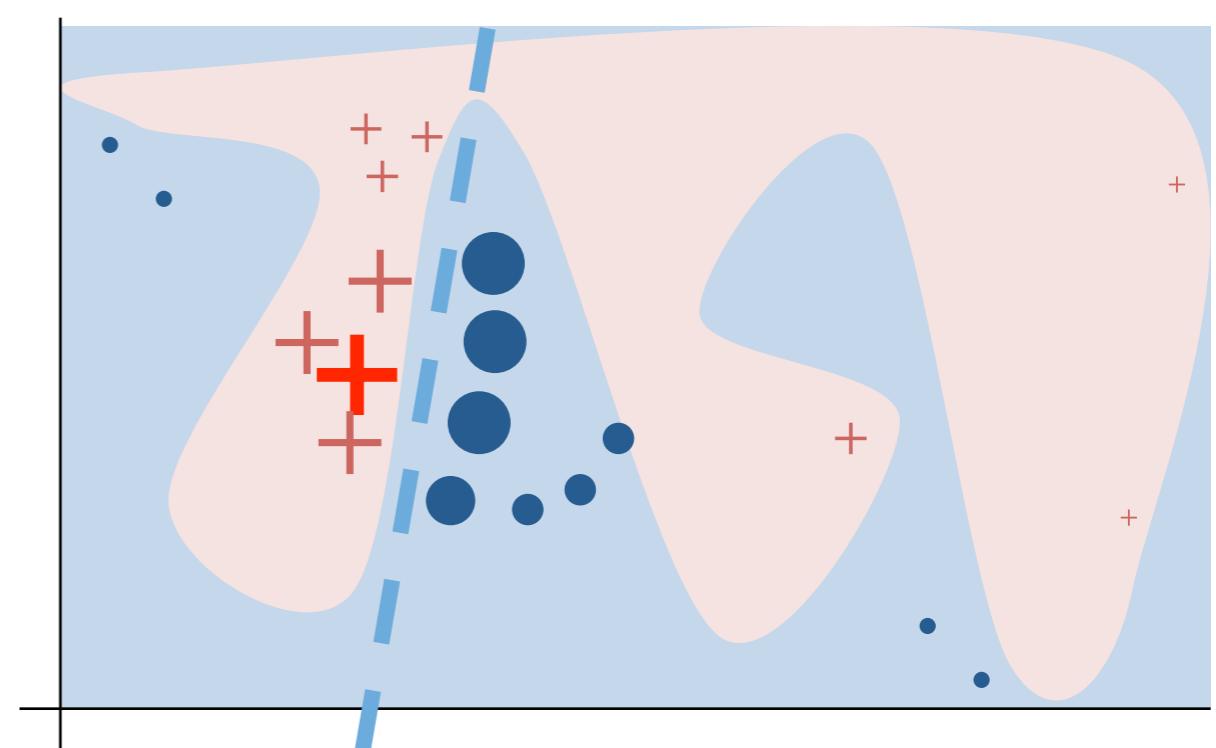

based on a slide by Marco Tulio Ribeiro, KDD 2016

# Fidelity-interpretability trade-off

[M. T. Ribeiro, S. Singh, C. Guestrin; KDD 2016]

“The overall goal of LIME is to identify an **interpretable** model over the *interpretable representation* that is **locally faithful** to the classifier.”

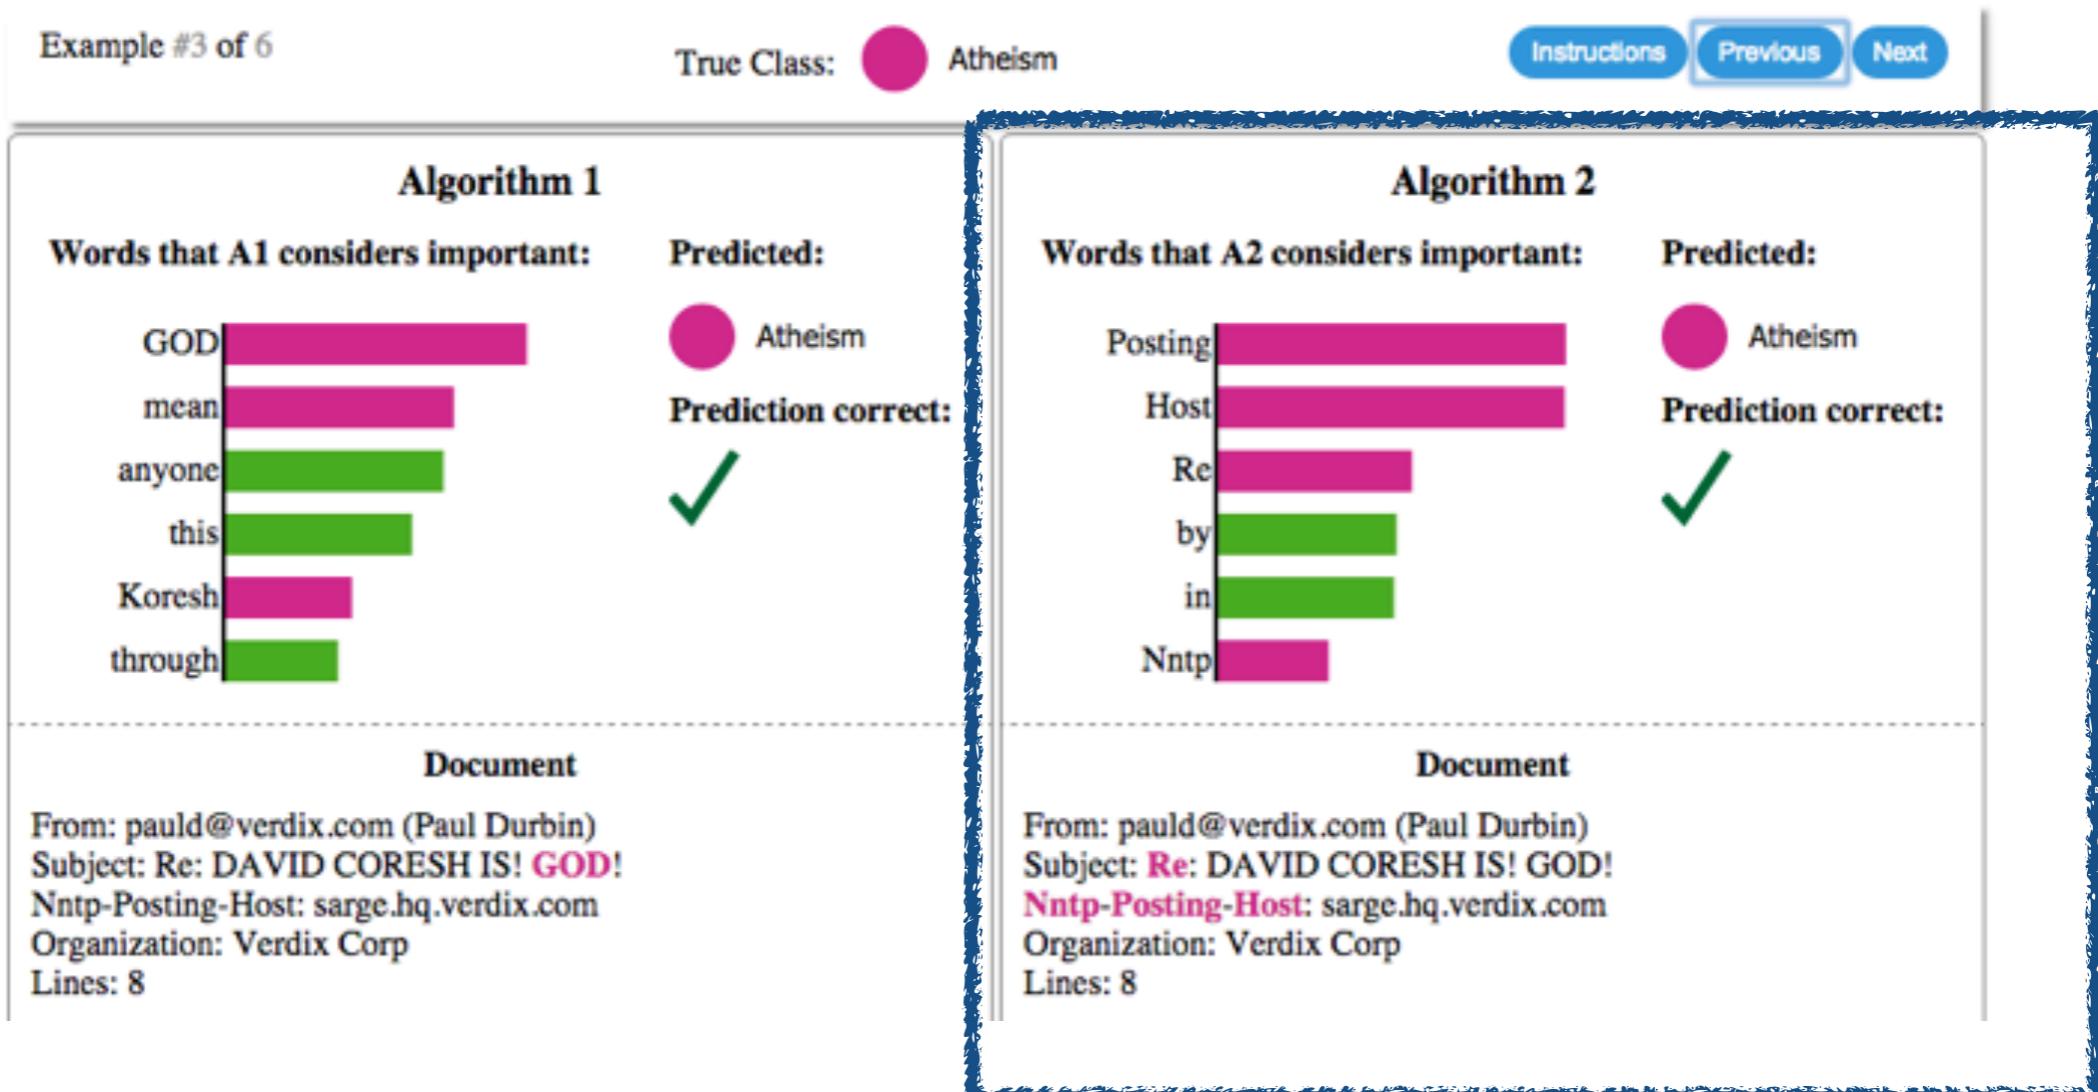

1. sample points around 
2. use complex model  $\mathbf{f}$  to assign class labels
3. weigh samples according to  $\pi_x$
4. learn simple model  $\mathbf{g}$  according to samples

based on a slide by Marco Tulio Ribeiro, KDD 2016

# Example: text classification with SVMs

[M. T. Ribeiro, S. Singh, C. Guestrin; KDD 2016]

94% accuracy, yet we shouldn't trust this classifier!

# Example: deep networks for images

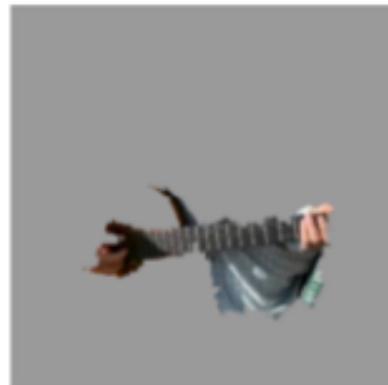

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

## Explaining Google's Inception NN

probabilities of the top-3 classes  
and the super-pixels predicting each

$P(\text{Electric guitar}) = 0.32$

Electric guitar (incorrect, but  
this mistake is reasonable -  
similar fretboard)

$P(\text{Acoustic guitar}) = 0.24$

Acoustic guitar

$P(\text{Labrador}) = 0.21$

Labrador

based on a slide by Marco Tulio Ribeiro, KDD 2016

# Example: deep networks for images

[M. T. Ribeiro, S. Singh, C. Guestrin; *KDD 2016*]

Train a neural network to predict **wolf** v. **husky**

Only 1 mistake!!!

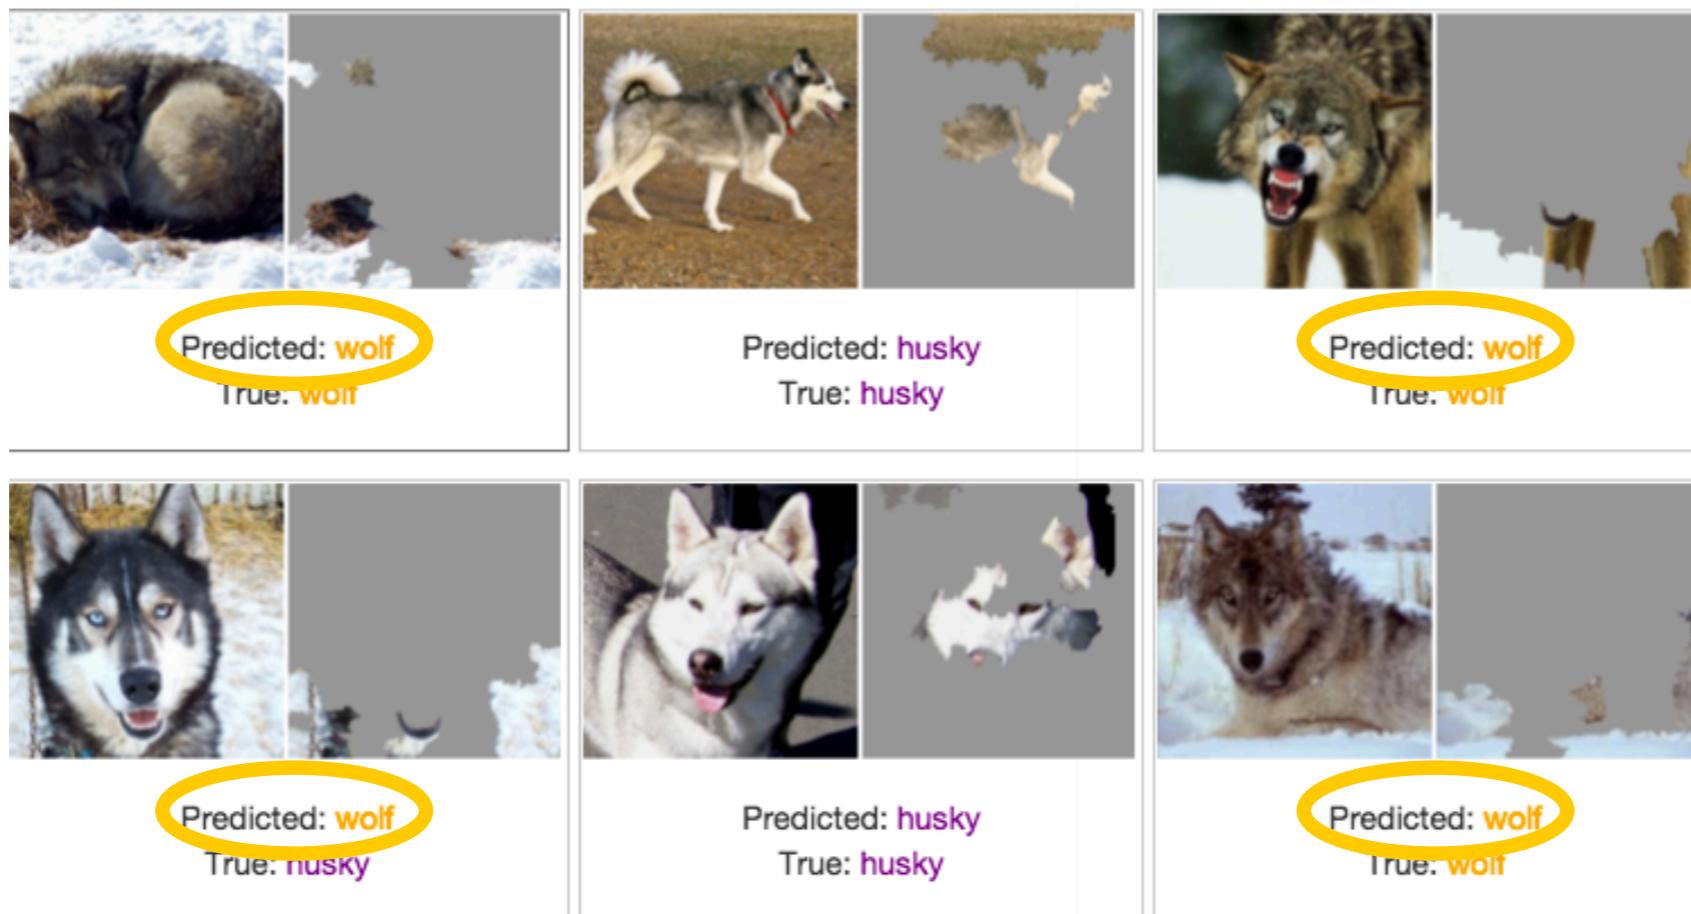

Do you trust this model?  
How does it distinguish between huskies and wolves?

slide by Marco Tulio Ribeiro, KDD 2016

# Example: deep networks for images

# Algorithmic transparency with quantitative input influence (**QII**)

[A. Datta, S. Sen, Y. Zick; *SP 2016*]

# Auditing black-box models

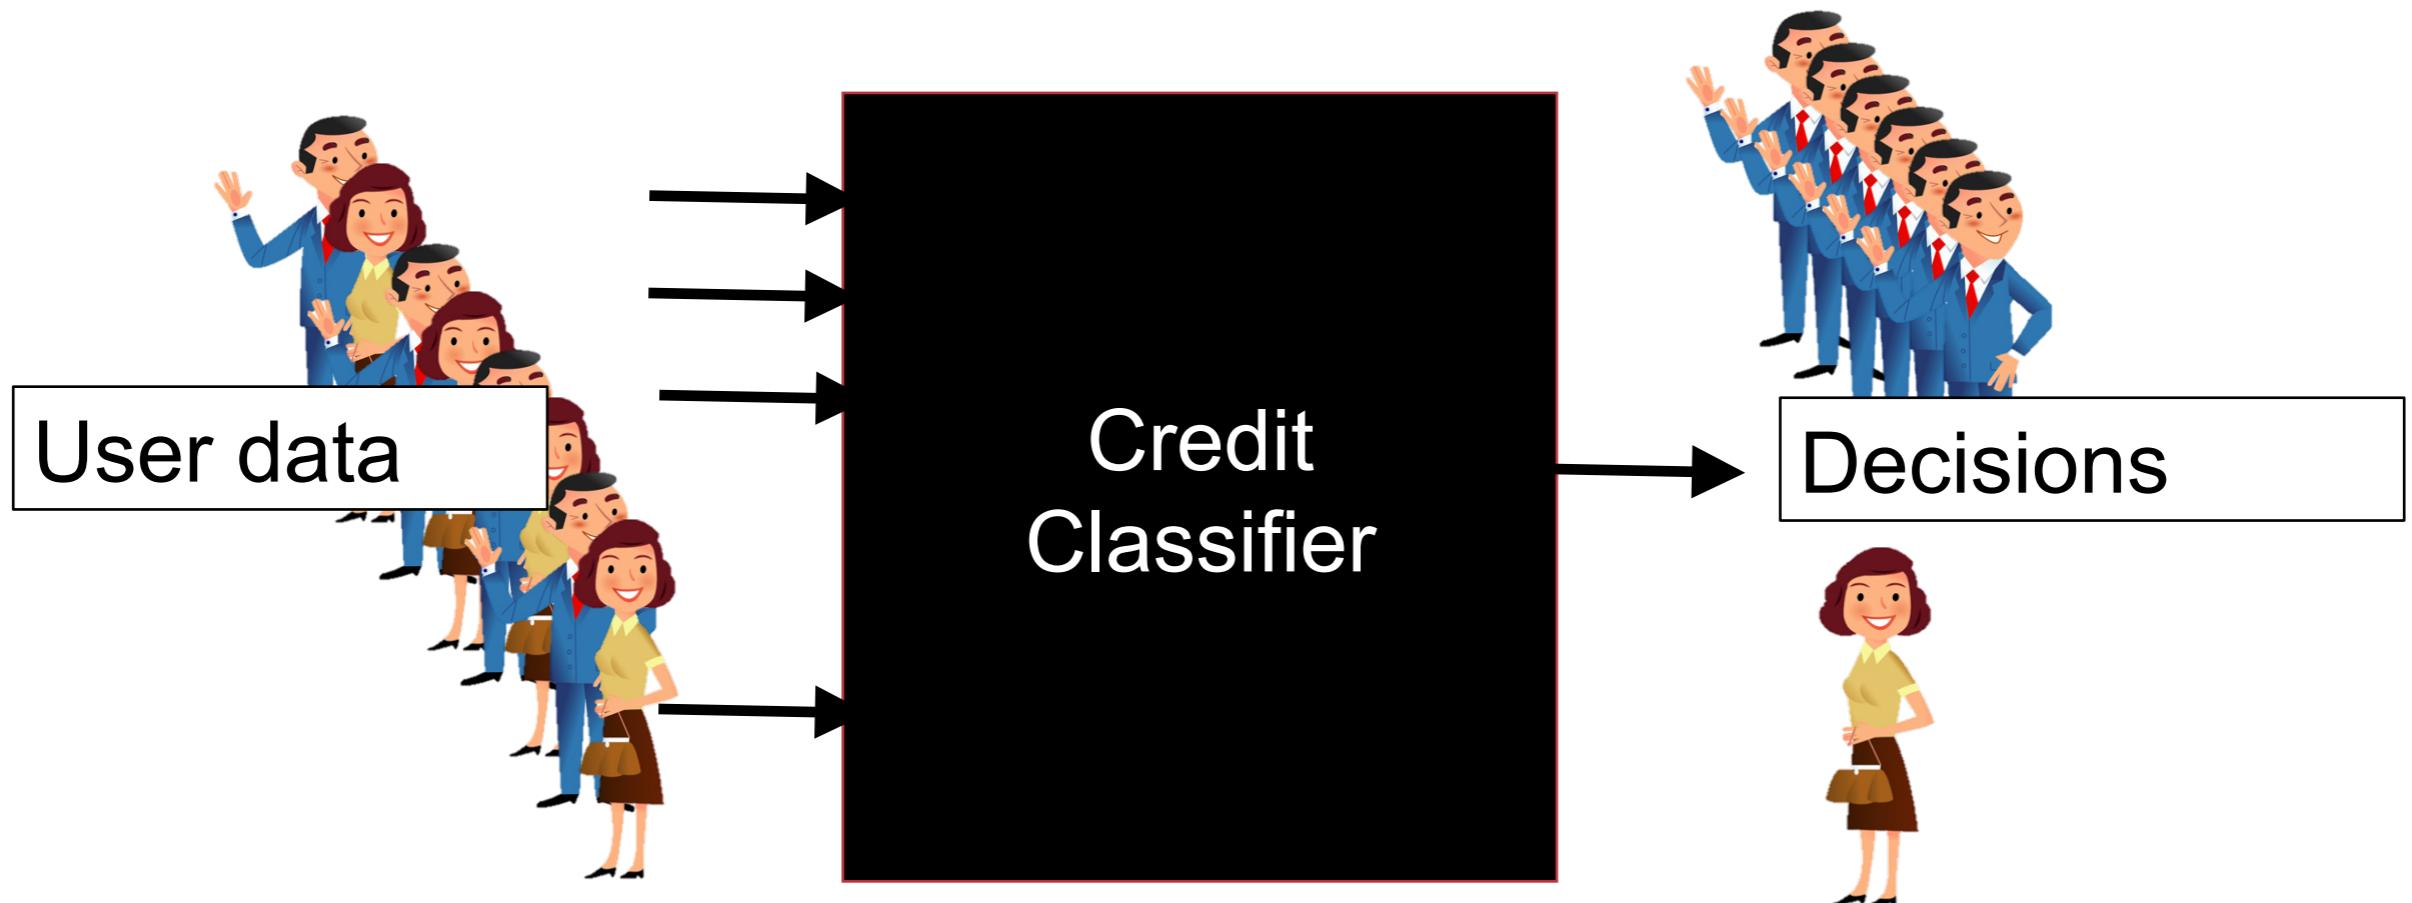

[A. Datta, S. Sen, Y. Zick; SP 2016]

slide by A. Datta

# Auditing black-box models

[A. Datta, S. Sen, Y. Zick; SP 2016]

slide by A. Datta

# Influence of inputs on outcomes

[A. Datta, S. Sen, Y. Zick; SP 2016]

**Running example:** Consider hiring decisions by a moving company, based on gender, age, education, and weight lifting ability. **Does gender influence hiring decisions?**

Possible answers:

- yes, directly
- yes, through a proxy
- yes, in combination with other features (will see an example later)
- no

**which of these constitutes discrimination?**

# Influence of inputs on outcomes

[A. Datta, S. Sen, Y. Zick; SP 2016]

**Running example:** Consider hiring decisions by a moving company, based on gender, age, education, and weight lifting ability. **Does gender influence hiring decisions?**

*“Gender and the ability to lift heavy weights are inputs to the system. They are positively correlated with each other and with the hiring decisions. Yet transparency into whether the system uses the weight lifting ability or the gender in making its decisions (and to what degree) has substantive implications for determining if it is engaging in discrimination (the business necessity defense could apply in the former case [E.G. Griggs v. Duke Power Co. (1977)]). This observation makes us look beyond correlation coefficients and other associative measures.”*

# Quantitative input influence (QII)

[A. Datta, S. Sen, Y. Zick; SP 2016]

**QII**: quantitative input influence framework

Goal: determine how much influence an input, or a set of inputs, has on a **classification outcome** for an individual or a group

Uses **causal inference**: For a quantity of influence  $Q$  and an input feature  $i$ , the QII of  $i$  on  $Q$  is the difference in  $Q$  when  $i$  is changed via an **intervention**

**Intervention**: Replace features with random values from the population, examine the distribution over outcomes. (More generally, sample feature values from the **prior**.)

Methodology works under **black-box access**: can specify inputs and observe outputs (as in software testing) but cannot access or analyze the code of the model. **Must have knowledge of the input dataset on which the model operates.**

# Back to the example

[A. Datta, S. Sen, Y. Zick; SP 2016]

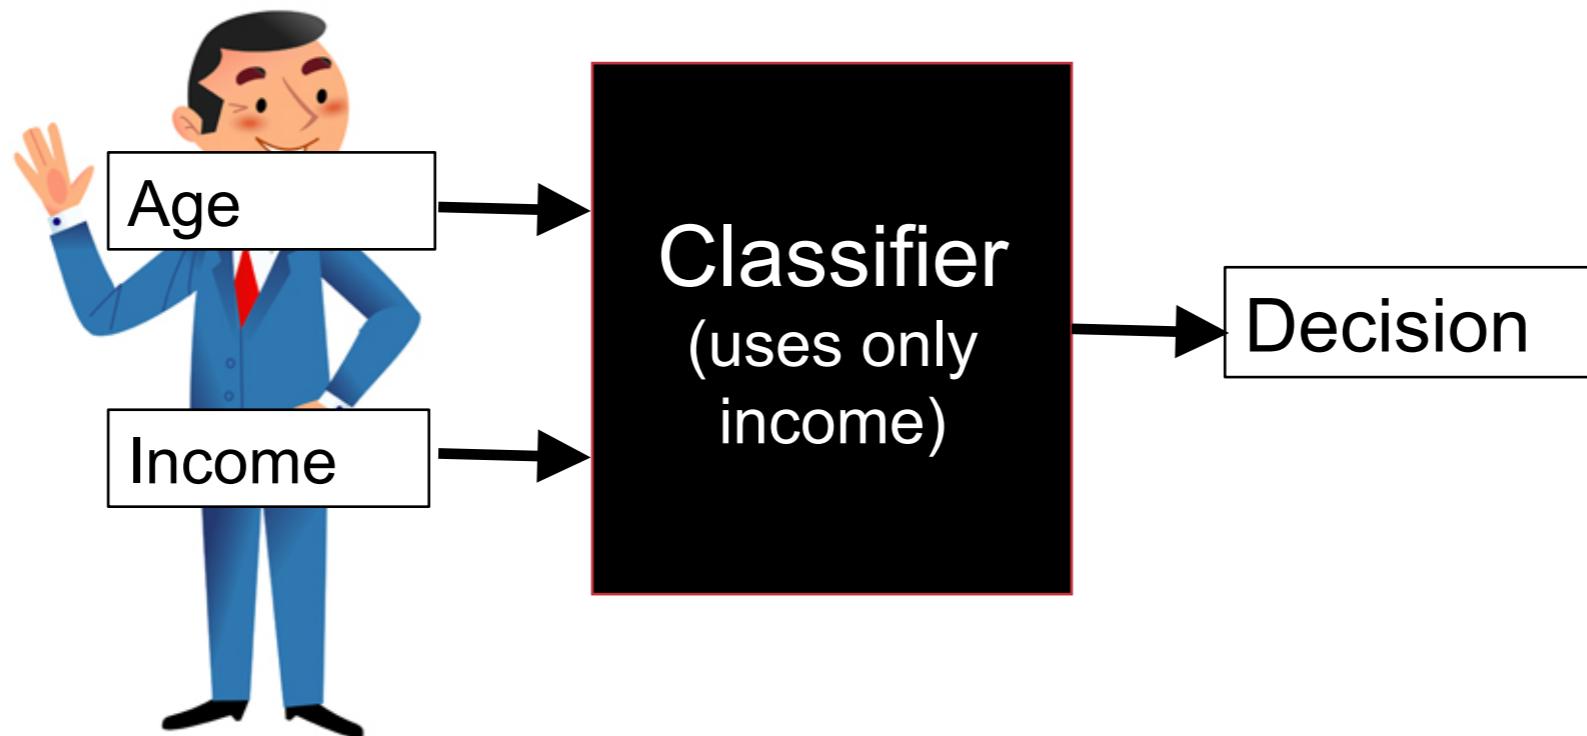

**Running example:** Consider hiring decisions by a moving company, based on gender, age, education, and weight lifting ability. **Does gender influence hiring decisions?**

- Observe that 20% of female profiles receive the positive classification.
- To check whether gender impacts hiring decisions, take the input dataset and replace the value of gender in each input profile by drawing it from the uniform distribution: set gender in 50% of the inputs to female and 50% to male.
- If we observe that 20% of female profiles are positively classified **after the intervention** - we conclude that gender does not influence hiring decisions.
- Do a similar test for other features, one at a time. This is known as **Unary QII**

# Unary QII

[A. Datta, S. Sen, Y. Zick; SP 2016]

For a quantity of influence  $Q$  and an input feature  $i$ , the QII of  $i$  on  $Q$  is the difference in  $Q$  when  $i$  is changed via an **intervention**.

replace features with random values from the population, examine the distribution over outcomes

slide by A. Datta

# Quantifying influence of inputs on outcomes

[A. Datta, S. Sen, Y. Zick; SP 2016]

**QII:** quantitative input influence framework

Goal: determine how much influence an input, or a set of inputs, has on a **classification outcome** for an individual or a group

## Transparency queries / quantities of interest

**Individual:** Which inputs have the most influence in my credit denial?

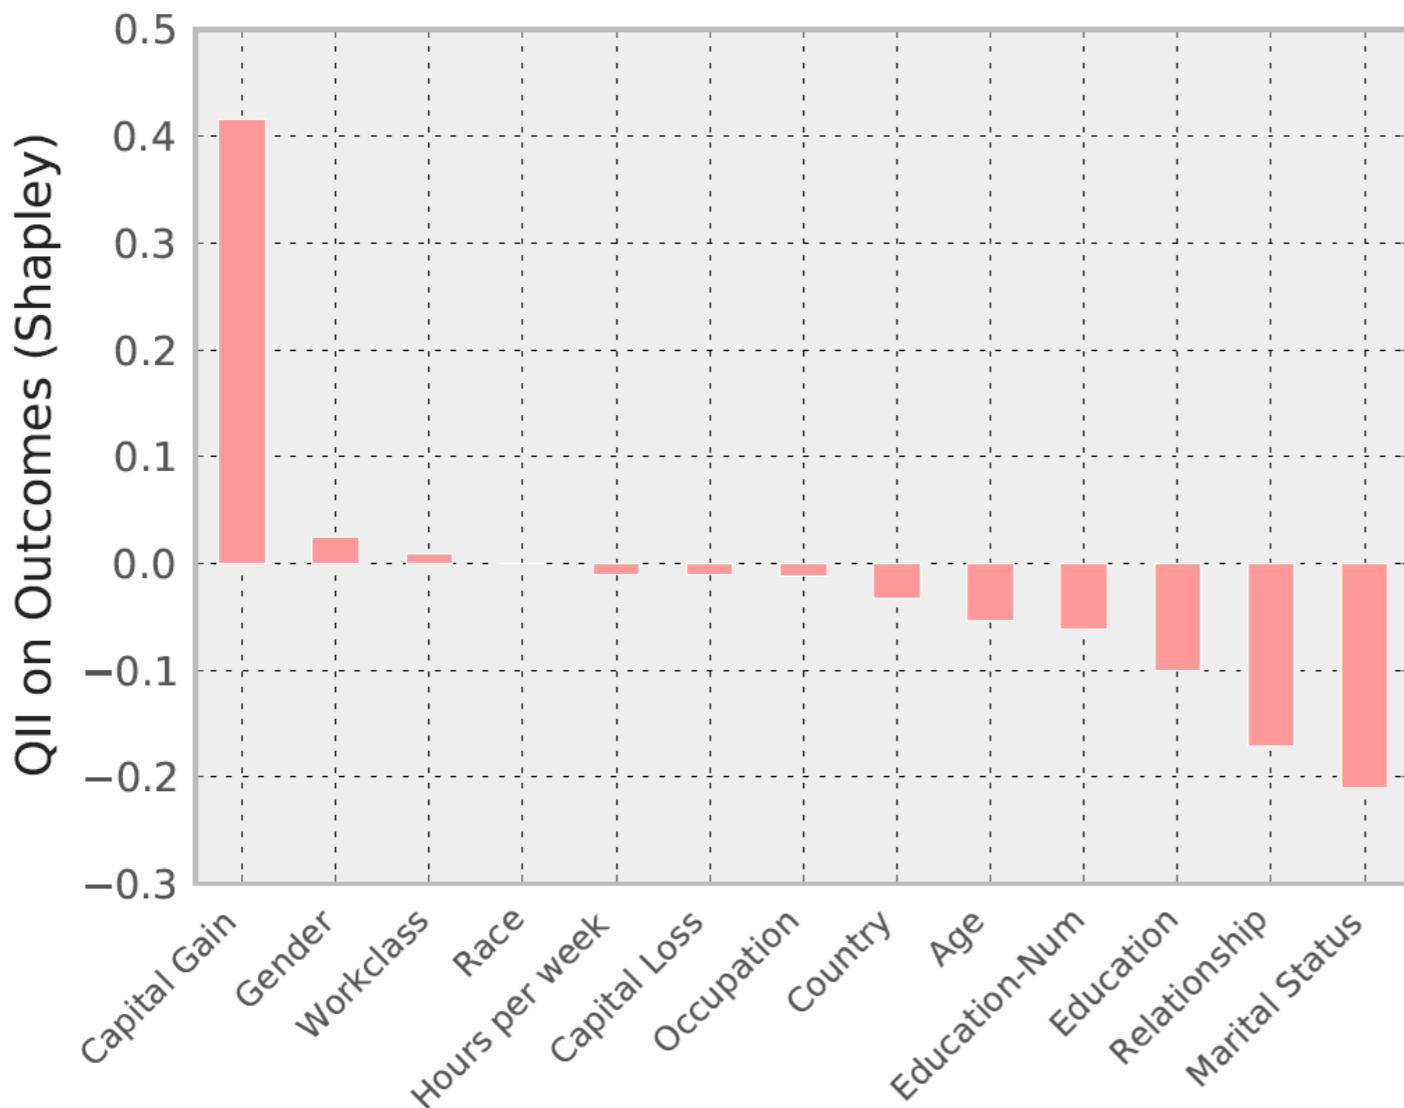

**Group:** Which inputs have the most influence on credit decisions for women?

**Disparity:** Which inputs influence men getting more positive outcomes than women?

# Transparency report: Mr X

[A. Datta, S. Sen, Y. Zick; SP 2016]

How much influence do individual features have a given classifier's decision about an individual?

# Unary QII

[A. Datta, S. Sen, Y. Zick; SP 2016]

For a quantity of influence  $Q$  and an input feature  $i$ , the QII of  $i$  on  $Q$  is the difference in  $Q$  when  $i$  is changed via an **intervention**.

replace features with random values from the population, examine the distribution over outcomes

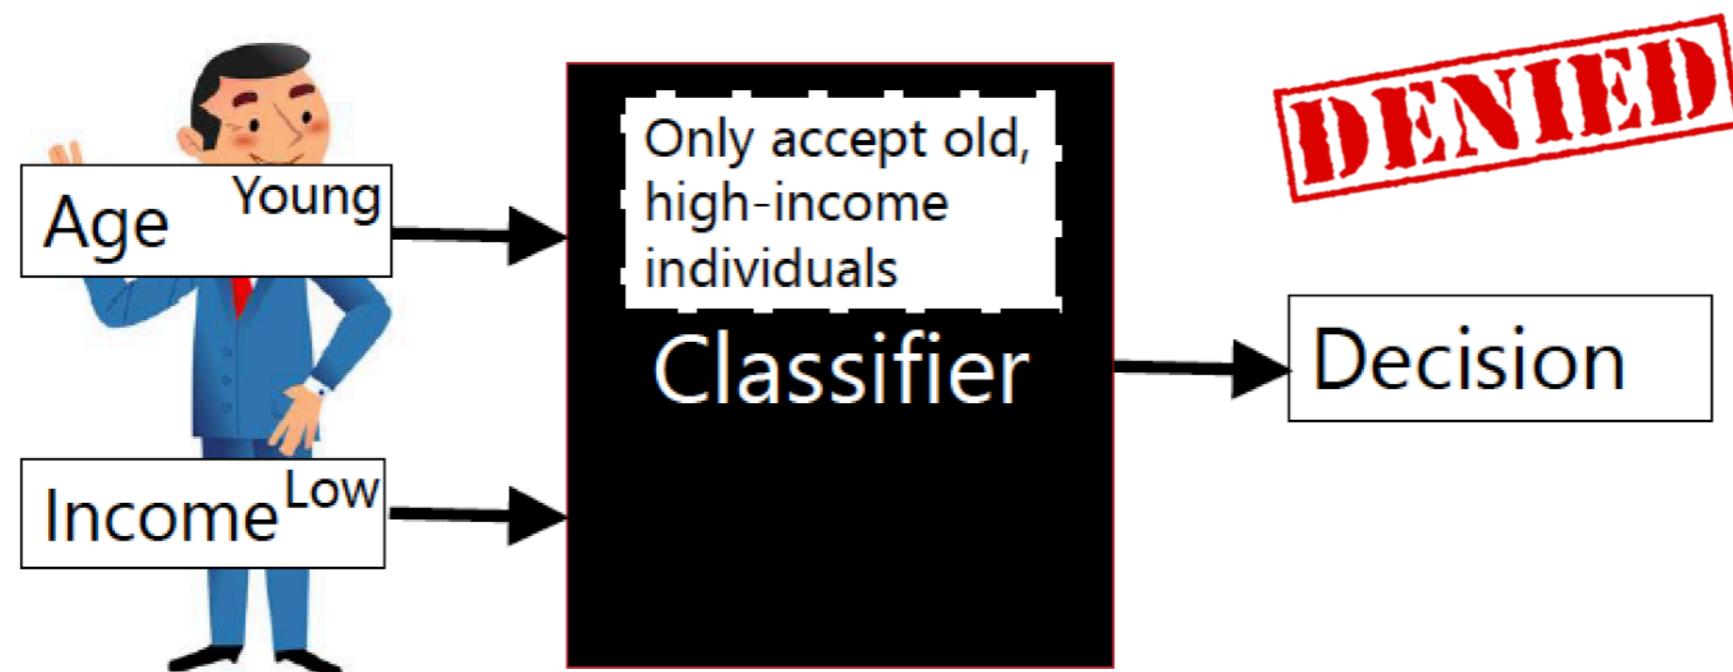

**does this tell the whole story?**

slide by A. Datta

# Limitations of unary QII

[A. Datta, S. Sen, Y. Zick; SP 2016]

For a quantity of influence  $Q$  and an input feature  $i$ , the QII of  $i$  on  $Q$  is the difference in  $Q$  when  $i$  is changed via an **intervention**.

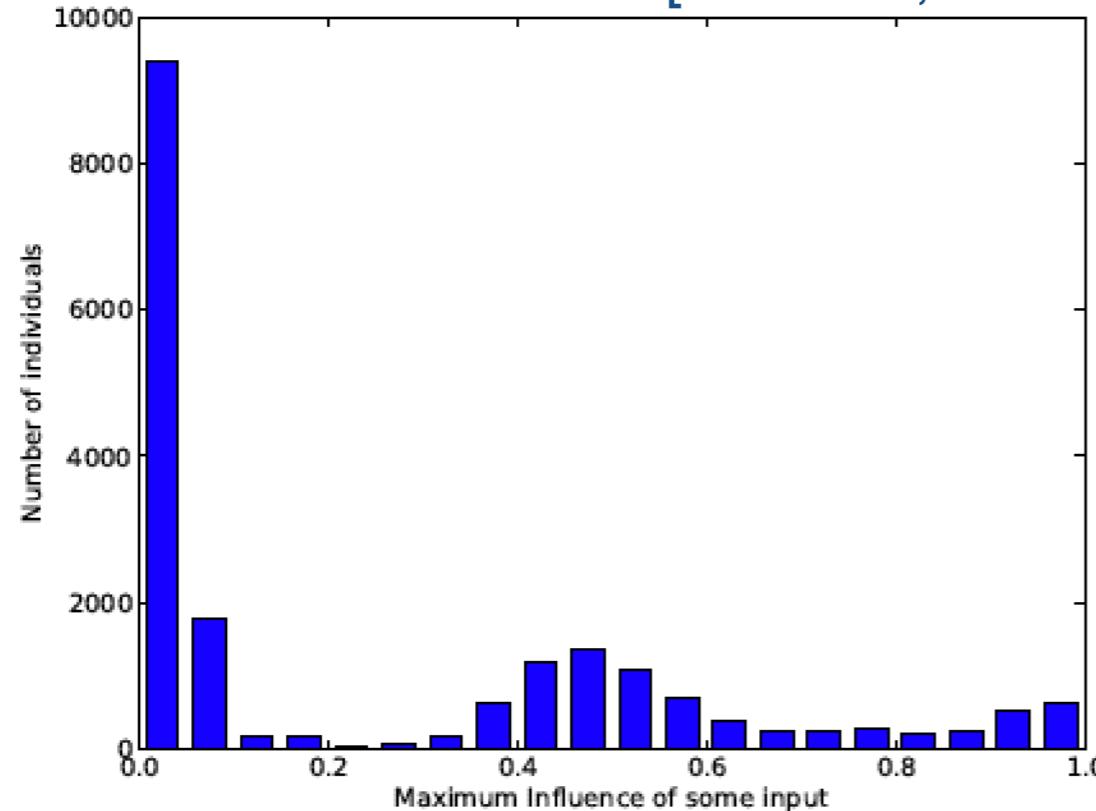

**intervening on one feature at a time will not have any effect**

based on a slide by A. Datta

# Set and marginal QII

[A. Datta, S. Sen, Y. Zick; SP 2016]

A histogram of the highest specific causal influence for some feature across individuals in the UCI adult dataset. **Alone, most inputs have very low influence.**

**Set QII** measures the **joint influence** of a set of features  $S$  on the quantity of interest  $Q$ .

**Marginal QII** measures the **added influence** of feature  $i$  with respect to a set of features  $S$  on the quantity of interest  $Q$ . Use cooperative games (Shapley value) to aggregate marginal influence

# Marginal QII

[A. Datta, S. Sen, Y. Zick; SP 2016]

- Not all features are equally important within a set.
- *Marginal QII*: Influence of age and income over only income.  
 $\iota(\{\text{age}, \text{income}\}) - \iota(\{\text{income}\})$

Need to aggregate Marginal QII across all sets

- But age is a part of many sets!

$$\begin{array}{ll} \iota(\{\text{age}\}) - \iota(\{\}) & \iota(\{\text{age}, \text{gender}, \text{job}\}) - \iota(\{\text{gender}, \text{job}\}) \\ \iota(\{\text{age}, \text{job}\}) - \iota(\{\text{job}\}) & \iota(\{\text{age}, \text{gender}\}) - \iota(\{\text{gender}\}) \\ \iota(\{\text{age}, \text{gender}, \text{income}\}) - \iota(\{\text{gender}, \text{income}\}) & \iota(\{\text{age}, \text{gender}, \text{job}\}) - \iota(\{\text{gender}, \text{job}\}) \end{array}$$

slide by A. Datta

# Aggregating influence across sets

[A. Datta, S. Sen, Y. Zick; SP 2016]

**Idea:** Use game theory methods: voting systems, revenue division

*"In voting systems with multiple agents with differing weights, voting power often does not directly correspond to the weights of the agents. For example, the US presidential election can roughly be modeled as a cooperative game where each state is an agent. The **weight of a state is the number of electors in that state** (i.e., the number of votes it brings to the presidential candidate who wins that state). Although states like California and Texas have higher weight, swing states like Pennsylvania and Ohio tend to have higher power in determining the outcome of elections."*

This paper uses the **Shapley value** as the aggregation mechanism

$$\varphi_i(N, v) = \mathbb{E}_\sigma[m_i(\sigma)] = \frac{1}{n!} \sum_{\sigma \in \Pi(N)} m_i(\sigma)$$

# Aggregating influence across sets

[A. Datta, S. Sen, Y. Zick; SP 2016]

**Idea:** Use game theory methods: voting systems, revenue division

This paper uses the **Shapley value** as the aggregation mechanism

$$\varphi_i(N, v) = \mathbb{E}_\sigma[m_i(\sigma)] = \frac{1}{n!} \sum_{\sigma \in \Pi(N)} m_i(\sigma)$$

$v: 2^N \rightarrow \mathbb{R}$  influence of a set of features  $\mathbf{S}$  on the outcome

$\varphi_i(N, v)$  influence of feature  $i$ , given the set of features  $N = \{1, \dots, n\}$

$\sigma \in \Pi(N)$  a permutation over the features in set  $N$

$m_i(\sigma)$  payoff corresponding to this permutation

# QII, in summary

[A. Datta, S. Sen, Y. Zick; *SP 2016*]

- A principled (and beautiful!) framework for determining the influence of a feature, or a set of features, on a decision
- Works for black-box models, with the assumption that the full set of inputs is available
- Accounts for correlations between features
- “Parametrizes” on what quantity we want to set (QII), how we intervene, how we aggregate the influence of a feature across sets
- Experiments in the paper: interesting results
- Also in the paper: a discussion of **transparency under differential privacy**

# A unified approach to interpreting model predictions (**SHAP**)

[Scott Lundberg and Su-In Lee; *NeurIPS 2017*]

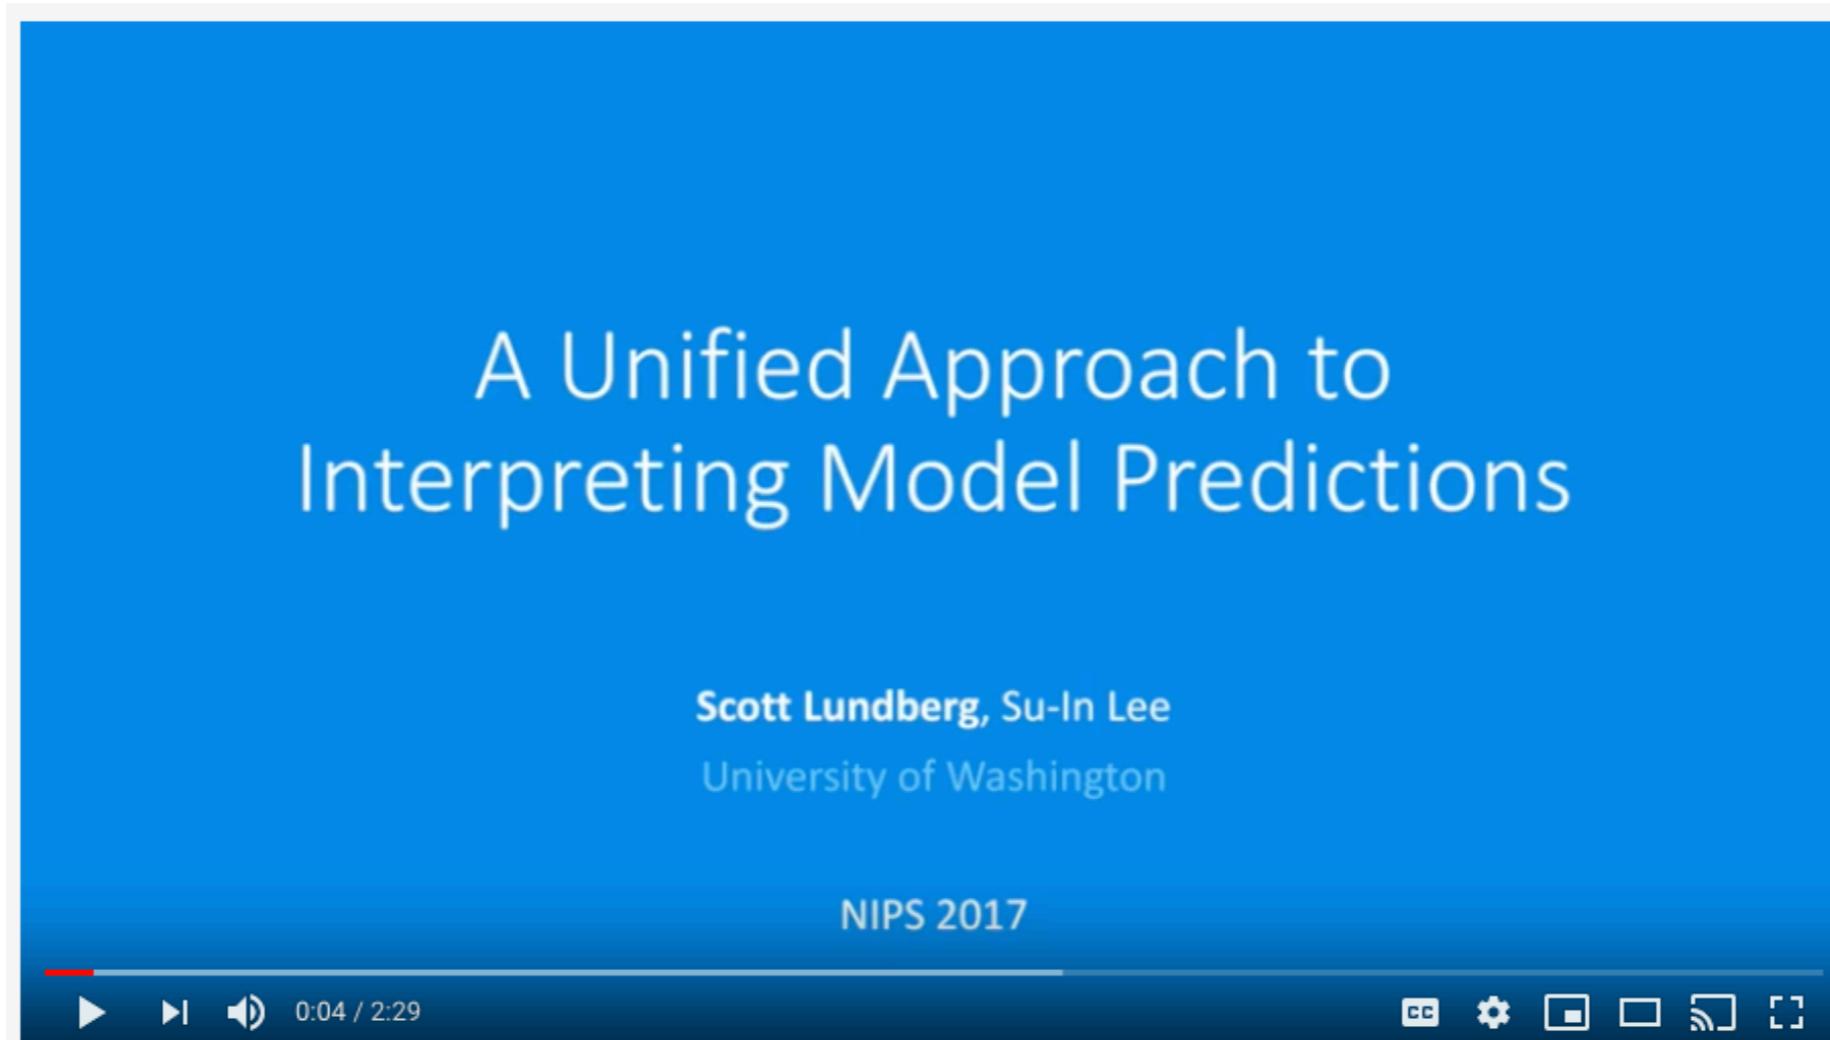

# SHAP, in summary

[S. Lundberg and S. Lee; *NeurIPS 2017*]

- **SHAP** stands for **SHapley Additive exPlanations**
- Claim: A unifying framework for interpreting predictions with “**additive feature attribution methods**”, including LIME and QII, for **local explanations**
- The best explanation of a **simple model** is the model itself: the explanation is both accurate and interpretable. For complex models we must use a simpler **explanation model** — an interpretable approximation of the original model.  
 $f : \mathbb{R}^d \rightarrow \mathbb{R}$   
**model being explained**  
$$g \in G, \text{dom}(g) = \{0,1\}^d$$
  
**explanation model** from a class of interpretable models, over a set of **simplified features**
- **Additive feature attribution methods** have an explanation model that is a linear function of binary variables

# SHAP, in summary

[S. Lundberg and S. Lee; *NeurIPS 2017*]

[https://www.youtube.com/watch?v=wjd1G5bu\\_TY](https://www.youtube.com/watch?v=wjd1G5bu_TY)

# Additive feature attribution methods

[S. Lundberg and S. Lee; *NeurIPS 2017*]

**Additive feature attribution methods** have an explanation model that is a linear function of binary variables (simplified features)

$$g(x') = \phi_0 + \sum_{i=1}^{d'} \phi_i x'_{\cdot i} \quad \text{where } x' \in \{0,1\}^{d'}, \text{ and } \phi_i \in \mathbb{R}$$

Three properties guarantee a single unique solution — a unique allocation of Shapley values to each feature

1. **Local accuracy**:  $g(\mathbf{x}')$  matches the original model  $\mathbf{f}(\mathbf{x})$  when  $\mathbf{x}'$  is the **simplified input** corresponding to  $\mathbf{x}$ .
2. **Missingness**: if  $x'_i$  — the  $i^{\text{th}}$  feature of simplified input  $\mathbf{x}'$  — is missing, then it has no attributable impact for  $\mathbf{x}$   $x'_{\cdot i} = 0 \Rightarrow \phi_i = 0$
3. **Consistency (monotonicity)**: if toggling off feature  $i$  makes a bigger (or the same) difference in model  $\mathbf{f}'(\mathbf{x})$  than in model  $\mathbf{f}(\mathbf{x})$ , then the weight (attribution) of  $i$  should be no lower in  $\mathbf{f}'(\mathbf{x})$  than in  $\mathbf{f}(\mathbf{x})$

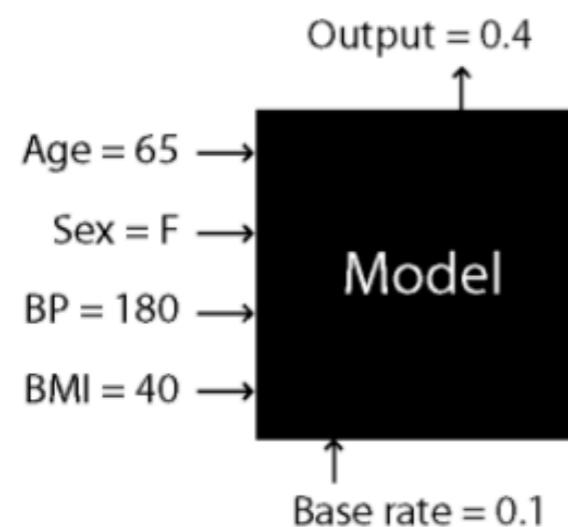

# Additive feature attribution methods
